# PROVINCE OF QUEBEC

## MINES BRANCH

Department of Colonization, Mines and Fisheries

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, etc.

MINISTER OF COLONIZATION, MINES AND FISHERIES, QUEBEC

**MINER'S CERTIFICATES.** First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is \$10 and is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

**WORKING CONDITIONS.** During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

**SIX MONTHS AFTER STAKING.** At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

**MINING LICENSE.** The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year, and a fee of \$10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days' labour on each forty acres.

**MINING CONCESSION.** Notwithstanding the above, a mining concession may be acquired at any time at the rate of \$5 an acre for SUPERIOR METALS, and \$3 an acre for INFERIOR MINERALS.

The attention of prospectors is especially called to the territory in the North-Western part of the Province of Quebec north of the height of land, where important mineralized belts are known to exist.

**PROVINCIAL LABORATORY.** Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, Montreal, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

**HONORABLE J. E. PERRAULT,**

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

# BRITISH COLUMBIA

## The Mineral Province of Western Canada

Has produced Minerals valued as follows: Placer Gold, \$76,177,403; Lode Gold, \$105,557,977; Silver, \$55,259,485; Lead, \$48,330,575; Copper, \$166,393,488; Zinc, \$21,848,531; Coal and Coke, \$225,409,505; Building Stone, Brick Cement, etc., \$34,072,016; Miscellaneous Minerals, \$1,210,639; Making its mineral production to the end of 1920 show an

**Aggregate Value of \$734,259,619**

The substantial progress of the Mining Industry of this Province is strikingly exhibited in the following figures, which show the value of production for successive five-year periods: For all years to 1895, inclusive \$94,547,241; for five years, 1896-1900, \$57,605,967; for five years, 1901-1905, \$96,509,968; for five years, 1906-1910, \$125,534,474; for five years, 1911-1915, \$142,072,603; for the year 1916, \$42,290,462; for the year 1917, \$37,010,392; for the year 1918, \$41,782,474; for the year 1919, \$33,290,313; 1920, \$35,543,084; 1921, \$28,066,641.

**Production During last ten years, \$336,562,897**

Lode-mining has only been in progress for about twenty-five years, and not 20 per cent. of the Province has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those of any other Province in the Dominion, or any Colony in the British Empire.

Mineral locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with Mining Reports and Maps may be obtained gratis by addressing.

**VICTORIA, British Columbia.**  
**THE HON. THE MINISTER OF MINES**

## American Zinc Lead and Smelting Co.

Purchasers of

# ZINC and LEAD ORES

Address

1012 Pierce Building, St. Louis, Mo.

## Exploration Department

For the purchase of

# MINES

Gold - Silver - Lead - Zinc - Copper

Address

55 Congress Street, Boston, Mass.

## The SYLVESTER Hand Car Motor

will save  
time and  
money for  
you

Can be attached to any standard hand car.

If you are already using pump or push cars on your surface tracks it will pay you to install this efficient outfit on them.

The extra work your men can accomplish and the time saved will soon pay for them.

We manufacture a complete line of hand cars — motor, pump and push types. Our equipment is in use on every railroad in Canada and giving excellent service.

Let us send a copy of our catalogue illustrating and describing our entire line.

## THE TURBINAIR "SLUSHER" HOIST.

For handling "slushers" or scraper loaders underground, or at stock piles or tailing dumps, this

### NEW SULLIVAN DOUBLE DRUM HOIST

secures rapid work with power economy and convenience.

In slushing, one drum hauls in the load, the other returning the scraper by a tail rope.

The motor runs continuously, and the clutch on each drum is thrown in or out with perfect control at all times as needed. Either drum is capable of hoisting 2,000 pounds vertically on 75 pounds air pressure, the same as the single drum hoist.

The light weight, [555 pounds,] and compactness of the Double Drum Turbinair make it convenient for use in sub-levels or other work in places that are hard to get at. The hoist is bolted to a skid or timber or mounted on a turntable if desired.

# Ontario's

# Minerals

PROVINCE OF ONTARIO

DEPARTMENT OF MINES

HON H. MILLS, Minister of Mines

## Mineral Areas.

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favorable for the occurrence of minerals, 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver mines of Cobalt occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

## Economic Minerals.

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario:—actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluor-spar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, portland cement, brick and tile, meet every demand.

## Mineral Production.

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1921 to be worth \$48,128,387, of which the metallic production was \$27,574,202.

The following figures show the rapid growth of Ontario's mineral industry by five-year periods since 1891:

| Year.      | Value.      | Year.      | Value.       |
|------------|-------------|------------|--------------|
| 1891 ..... | \$4,705,672 | 1906 ..... | \$22,388,383 |
| 1896 ..... | 5,235,003   | 1911 ..... | 41,976,797   |
| 1901 ..... | 11,831,086  | 1916 ..... | 65,308,822   |

## Dividends.

Dividends and bonuses paid to the end of 1921 amounted to \$23,140,734 for gold mining companies, and \$84,388,185 for silver mining companies or a total of \$107,528,919.

## Mining Regulations.

A miner's license costs \$5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of \$2.50 or \$3.00 per acre, depending on location in unsurveyed or surveyed territory.

## Assay Office.

The Provincial Assay Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

## Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

## Publications.

For list of publications, illustrated reports, geological maps and mining laws, apply to

THOS. W. GIBSON,  
Deputy Minister of Mines,  
TORONTO, CANADA.

## CANADIAN COAL FOR CANADA

Nova Scotia coal has been publicly slighted. In his recent annual report to the share-holders as president of the Montreal Light Heat and Power Company, Sir Herbert Holt says: "Owing to the failure of United States sources [of coal supply] by reason of mining and railroad strikes, the major portion of our supply had to be imported from England at abnormal cost and inconvenience as regards handling and utility."

What about Nova Scotia coal for the Montreal gas works? The gas used in Montreal is made normally from imported coal, brought in by rail, and the use of water-borne coal, whether from Nova Scotia or elsewhere, does not come within the calculations of the managers of this concern. Why is this? The obvious deduction from Sir Herbert Holt's statement, without explanation, is that Nova Scotia coal is not suitable for use in a gas works. This is not the case. The fact is that the Montreal gas works is not suitable for the use of Nova Scotia coal.

The coal of Nova Scotia runs from 2 percent upwards in sulphur, as does coal from almost all the world's coal fields. It is unusually low in ash and is a good coking coal. It should be used in the Montreal gas works, but cannot be at present. Sir Herbert Holt naturally would not wish to bring this fact forcibly to the attention of the share-holders of his company; but it should be stated publicly in defence of our own coal. The plant of the Montreal gas works is somewhat antiquated, and was built for the use of coal unusually low in sulphur, obtainable only in selected coal fields in the United States, from certain collieries in Wales, and in a few other districts. The use of Nova Scotia coal in the present plant would result in gas contaminated with sulphur.

The obvious and rational procedure, now that Canadians are alive to the necessity of using their own coal as far as possible, is for the Montreal Light, Heat and Power Company to make such addition and alterations to its gas plant as will permit of the use of coal from Nova Scotia by removing the sulphur from the gas. We do not know whether or not this would be more economical than the use of imported coal; but we do know that it will be principally by means of such action on the part of large consumers of coal that our present huge bill for imported coal will be reduced and Canadian collieries kept working to capacity.

## BRITISH MONEY FOR CANADIAN MINES

A recent visitor to Canada from Scotland, who has been studying Canadian trade conditions for the past six months as an official observer from Glasgow, has contributed an informing and suggestive article to the current number of "Agricultural and Industrial Progress in Canada," an official publication of the Canadian Pacific Railway. His instructions were to investigate:

(a) The increased source of supply for raw materials in British industries and for food stuffs and finished articles.

(b) Scope for the future investment of British capital overseas, and

(c) The development of production, whether of raw materials or manufactured goods.

After dubbing Canada "the Scotland of North America" and pointing out the numerous points of similarity that warrant the comparison, Mr. Cuthbertson concludes: "It appears to me that Canada's most urgent needs at the present time are two in number — men and capital. She is short of these, while it is just these that Scotland has to give. The old land has men of the right sort, and capital for the right kind of undertaking. If, however, Canada desires them she must offer them the right kind of inducement."

This conclusion has a direct application to our mining industry.

It has been stated occasionally that for the capital needed to develop our mineral areas we must turn to the United States, as the war made such a heavy drain upon private fortunes in Great Britain that we can expect little financial aid from that source. Here are words from an official representative of capital in Scotland that give the lie to that conclusion. Scotland has capital "for the right sort of undertaking." Mark these words.

Some months ago we had letters from an investor in Glasgow who had bought shares of Matachewan Gold Mines, which had been distributed quite widely in that part of Scotland. He had tried without success to get information from the headquarters of this company about the progress of its undertaking and its financial status. Now it appears as if this Scot had not been quite canny enough in his investment. He had trusted the good faith of the promoters of Matachewan Gold Mines, apparently without warrant. Canadian gold mining will leave a bad taste in the mouths of this Scottish investor and the friends on

whose behalf he made inquiry to the "Journal". They were unlucky, or indiscreet, in choosing the **wrong** sort of undertaking.

But there is a brighter side to the story. It has been known for some months that a number of the more substantial mining "groups", in London have local representatives in this country, quietly making a thorough examination of the various mining fields. These groups are in no need of advertisement and shun publicity until it is thrust upon them or until their plans have matured. Their representatives have travelled strictly "incog." and have, we expect, searched out a number of the more promising prospects and *bona mines*. A press cable from London announces that the National Mining Corporation and the New Consolidated Gold Fields have collaborated in the formation of a new company, Porcupine Gold Fields Development and Finance Company, for the purpose of investing in the gold fields of Northern Ontario and elsewhere in Canada. These two British companies are closely inter-related, the second being the old Consolidated Gold Fields of South Africa is the new form it assumed in 1919. Both are essentially investment companies, with world-wide interests.

We hope that the forming of this new company marks the commencement of British investment in Canadian mines on a scale that will ensure the control by Britons, here and elsewhere, of the major part of this national resource. The instance we cited above of indiscriminate investment is typical of the means whereby a mining district is given a "black eye." The green-ness of far-away fields will be reduced to the true colour if British investors will make use of the eyes of accredited mining men in London. We welcome the announcement of the new investment company, as an indication that at last British investors, both large and small, will have an opportunity to put their money into genuine mining development in Canada.

### A NARROW ESCAPE

The eastern members of the Canadian Institute of Mining and Metallurgy do not want to restrict the membership in the way proposed by certain western members. This conclusion was unanimous at the meeting in Montreal two weeks ago. As there was no representative present of those that have supported the proposed amendment to the by-laws on membership, there was not even any effective discussion of the question. The only point brought out was that a restricted membership would mean an impaired income — a point that is only on the fringes of the problem.

On this occasion the annual meeting of the Institute came very near to disgracing itself. It was saved, curiously enough, by one of the very members whom our western confrères would have us exclude. A

motion voting down the proposed by-law had been adopted unanimously, and all, from the chairman to the youngest member, were apparently ready to let the matter rest there. It was a non-professional member, better versed in the ways of the business world and of business meetings than are the majority of the Institute's members, who put in a plea for the absent westerners, who have been honest and sincere in their attention to Institute affairs. Once again the meeting attempted to turn the occasion into a joke, and again this non-professional member insisted that the proposal of the western members be treated seriously. Reason prevailed, and the meeting was saved from disgrace.

There is a moral to this tale. We professional miners are rather an all-round lot, with experience in numerous fields of human endeavour. Nevertheless we have not yet corralled the sum-total of human wisdom, nor are we likely to accomplish that laudable end for some time to come. In one direction our education is as yet decidedly incomplete — the direction indicated above. It will be some years before we shall be able to dispense with the aid and advice of men in the great business and financial world outside professional mining. We need the coöperation of these men at this present moment to a greater extent than we realize. The mining industry is the one great national industry whose financial status is still in such a state of primitive chaos that the term "mining investment" provokes a smile from the wise, a grimace from those that have been "stung", a wink from the broker, and a look of interest only from the rare bird who either has won on the gambler's chance or has followed his nose to success.

We need the advice and aid of men in business and financial circles. We shall be wise to secure the active coöperation of those already included in our membership and, as occasion may direct, to enlist the aid of others not yet associated with our fraternity.

### THE NEW KEELEY STOCK

The rapid and sensational rise of the Keeley mine in silver production is a decided source of satisfaction to the mining industry of Canada. Dr. J. Mackintosh Bell has earned the congratulations of his fellow-Canadians both on account of his good judgment in choosing the then discredited Keeley as an investment for his principals in London, and on account of his persistency in pursuing exploration until the soundness of his geological reasoning had been demonstrated. Seldom has the practical application of scientific deduction reaped such a rich reward.

There appears to be a danger, however, that this creditable result of Dr. Bell's labours will be put to a use that will bring discredit in its wake. The Keeley has now some wonderful ore-shoots, found after toil-

some search along a deep-buried contact. It is only in the nature of things that the ore-shoots that have "come in" so rapidly will "pinch out" just as suddenly. There is no doubt that the amazingly rich ore now in sight or immediately in prospect will afford hundreds of thousands of dollars of profit to the owners. Recent events indicate that these owners, not content with the profit they have made and will make from their mine, are preparing to make a further amount from the speculating public by means of the stock market. Only thus can we interpret the recent conjunction of a rich and much-advertised display of ore, the incorporation of a new company on this continent (where there is already a wide market of the speculative variety) and the declaration of an eight percent dividend.

Already too many of our genuine mines have been put to the baser uses of the Canadian mining stock exchanges. These exchanges have an unenviable reputation and are not, and cannot be, patronised by discerning investors. The typical patron of the so-called broker of mining stocks in this country is in virtually the same position as the patron of the race-track book-maker. It is a pity the owners of the Keeley have made a move that will inevitably class them as confrères of the professional book-maker. They had much better decided to keep within the pale as honest miners.

### MINING AND SETTLEMENT

In the voluminous discussion on the immigration "policy" announced recently in the House of Commons, Ottawa, we have as yet found no statement to show that our legislators realize the important part mining development plays in the settlement of the land. We see our government proposing to dole out a little money here and a little money there to aid existing agencies for colonization, but we find no general policy adequate to the need, nor any balanced discussion of the factors that are constantly at work, with or without government subvention, populating the vacant spaces of our land. Among these natural agencies for settlement mining is one of the most important.

How many of the fertile valleys of British Columbia would now be growing their varied crops had not the mining booms proved an irresistible attraction to the pioneers, and the mines thus opened up brought in the railways? The fields and orchards will yield their harvest, long after the mines are worked out; but to the mines belongs the credit of most of the settlement. How much of the fast-filling section of the Great Clay Belt along the Temiskaming and Northern Ontario Railway would now be occupied had not Cobalt, Porcupine and Kirkland brought the thousands of men and their families and provided one of the most lucrative markets for farm produce in Ontario? If gold mines should be established in northwestern Quebec,

settlement in that eastern end of the Great Clay Belt will receive an impetus greater than that provided by ten times the meagre \$600,000 subsidy our Federal government proposes to spend on immigration during the coming twelve-month.

Legislation, or even subsidised immigration, can have comparatively little effect on the settlement of the land compared with the great natural forces that compel migration of the human species. The lure of gold has peopled permanently many parts of the world that would otherwise have waited for a century for settlement. It would have been encouraging to find a recognition of this important fact in the recent discussion in Ottawa—a discussion that matches in barrenness of constructive thought the government's totally inadequate proposals in aid of immigration.

Eleven essays were submitted for the President's prize competition to the Canadian Institute of Mining and Metallurgy this year. The winners were V. S. James and G. H. Salton of Queen's University and C. R. Whittemore of McGill University. Their papers were excellent, as were a number of the others.

### THE DUD

The Gillies Limit rush was on;  
The boys was in the air.  
They talked a lot of bull and con.  
And swung the lead for fair.  
We all had claims for to record,  
But that there darned Recorder  
He kep' us waiting round, my lord!  
To do the thing in order.  
Recorder's office it was shut,  
Sure it was closed till ten,  
When it would open for us — but  
It was uncertain when,  
Or if, we'd get a chance to file:  
The'h was an awful jam;  
The crowd it stretched near half a mile.  
You couldn't wedge or ram  
A bloomin' inch ahead or back.  
Then — sumpin' seemed to break—  
I seen my pardner, Whiskey Jack  
Put out his arm and shake  
A lighted fuse stuck in a stick  
Of healthy dynamite!  
The fuse was sparking good and quick—  
My G--d, it was a fright!  
Says Jack — "Now fade, yeh suckers, fade,  
"I've got the right of way!"  
And say, we sure did make the grade,  
Nobody tried to stay.  
Well, Jack recorded both our claims,  
Then he come sauntering back.  
I asts him why in h-ll he aims  
At pullin' such a crack?  
Well, for a time he shook his head;  
But soon I make him tell:  
That ca'tridge that had scared us dead  
Was filled with sawdust—h-ll!

J. C. M.

# Progress in British Columbia

Gold, Silver, Copper, Lead and Zinc Mines and Smelters Promise Increased Production for 1923

BY ROBERT DUNN

## Copper

With copper hovering round 15 cents the British Columbia copper mining situation has improved. The prospects are that the production of this metal will be largely increased in 1923 in comparison with the previous year.

There are plenty of signs pointing in this direction. One is the activity of the Granby Consolidated Mining & Smelting Co. at Anyox and its action in acquiring the Copper Mountain holdings which, with adequate capital available, should soon be put on a shipping basis. Another is the resumption of operations by the Britannia Mining & Smelting Co. at Howe Sound under conditions that assure a steady flow of material to the new mill and regular shipments of concentrate. A third is the construction of the new Kimberley Mill of the Consolidated Mining & Smelting Co. which, when completed, is expected to lead to the re-opening of the Rossland Mines in a large way. These are the outstanding developments, the progress of which must have an encouraging effect on the many smaller copper and other properties whose owners have been marking time in recent months.

## Silver—Lead—Zinc

But it is not alone the field of copper in which the Province is finding its feet. Could anything be more striking than the strides that are being made by the Consolidated, the pulsating heart of whose industry is found in the mountain-bound smelter town of Trail, perched on the banks of the mighty Columbia river? In the winning of the minerals of the "Big Sullivan" there have been brought to bear the most modern mining methods, applied on such a scale that the ore is pouring into the smelter in hundreds of tons daily. Through the concentrated effort of a group of highly trained and efficient metallurgists the problem of the economic treatment of this decidedly complex lead-zinc ore has been solved with the result that there emerges from the concentrating and smelting plant a production of these two metals that is succeeding in more than holding its own in the world's markets. In quantity the output has been steadily rolling upwards, reaching proportions last year whose industrial significance is as yet little appreciated. As practically all British Columbia's lead and zinc come from Trail, the official provincial statistics for the years 1919, 1920, 1921 and the estimates for 1922 tell the story most effectively. They follow:

|       | 1919       | 1920       | 1921       | 1922        |
|-------|------------|------------|------------|-------------|
|       |            |            |            | (estimated) |
| Lead: | 29,475,968 | 39,331,218 | 41,402,288 | 48,231,000  |
| Zinc: | 56,737,651 | 47,208,268 | 49,419,372 | 59,010,000  |

These figures, of course, give the production in pounds. It is to be noted that, despite occasional adverse market conditions, lead has not failed to show an increase throughout the four year period. The explanation of the slump in zinc in 1920 will occur to all who have been following the markets and it is remarkable that the improvement last year in the market was so quickly made evident in the output. This is not to be attributed so much to outside influences, however, as to the triumph of the metallur-

gical staff of the Consolidated in surmounting difficulties that for so long had seemed insuperable.

## The Kootenays

Whatever may be said in criticism of the policy of the Consolidated in respect of the treatment of custom shippers, there can be no effective denial of the fact that the industry for which it is responsible is the nerve centre of the Kootenay mining camps. Disagreements have occurred in the past. Commissions have examined charges made against the Company. Doubtless misunderstandings will recur. At present it is gratifying to be able to record that good feeling exists between the independent operators and the Company. The hatchet has been buried and the dove of peace has spread her wings over that section of the country. Whatever the future has in store, nothing can detract from the credit due the Company. It has done and continues to do a wonderful work for the mining of the Kootenays of British Columbia and as long as the exigencies of business and the diversified needs of independent operators can be kept harmonious, mining will flourish.

## Portland Canal

Wherever one looks, optimism prevails. In the Portland Canal District the Premier Mine, through recent discoveries, has an assured future. "I have been 31 years in the mining business," stated an elderly engineer just down from the North. "Too many promising properties have sprung up under my eyes, prospered exceedingly for the moment and died away, for me to be easily deluded. I had thought it possible that the Premier Mine was a thing of the day, to peter out and be quickly forgotten. After making a personal examination, granted through the courtesy of the management, my confidence is complete. The Premier is a Mine. Development at depth has proved that beyond dispute. The B. C. Silver, just adjacent, is working in ore of similar character, although the high-grade has not been uncovered." This man speaks for the whole camp. Any doubt that existed has been wiped out, there will be much capital invested in opening up prospects this summer, and the Government, as stated by Hon. T. D. Pattullo, Minister of Lands, when on a visit to Stewart a few weeks ago, will make substantial expenditures in those parts this year. This will go into road and trail construction, one notable undertaking being a permanent bridge across the Bear River, giving access from Hyder and Stewart to the upper Bear River region.

## Cariboo

Cariboo, too, promises to be revived. The Cedar Creek field, with its production of some \$120,000 in a few months by means of the rocker and other primitive expedients, had brought back, in a measure, the old days of the export of bullion in stages and under armed guard. It seems likely that those who took over the original leases, agreeing to pay large sums therefor, will be able to make all their payments in the yield of the ground. Possibly they will reap, in addition, fortunes for themselves. At any rate this

much is certain, that the golden reward of their efforts already is centering attention of prospectors on the possibilities of the Cariboo, that there will be hundreds in the field this Summer, and that hydraulicking, and even dredging, operations will be undertaken on old and new ground on a much greater scale than has been witnessed for years.

Other healthy indications might be quoted. The gratifying reports of developments in connection with the Belmont Surf Inlet Mines Ltd. Princess Royal

Island; the energy displayed in opening up the Drum Lummon Mine, Hartley Bay; the announced determination of the Provincial Department of Mines in co-operation with the Canadian Geological Survey to definitely ascertain by thorough exploration the provincial resources in iron ore; recent discoveries in the Whitewater section of the interior; and the richness of some properties being exploited in the Hudson Bay Mountain zone are among the many incidents pointing to progress.

## THE PROSPECTOR IN WINTER

BY TOM SAVILLE

My love for adventure has lured me into some strange places, but this was the limit. Here I was already on my way North to interview Hudson's Bay Bill, a prospector, who might be any place between Cobalt and Conjuror's House, and in the middle of winter. Our daily paper, "The Planet" was running a series of articles, "The Wood and Woodsman," which had started quite a controversy, the climax of which was reached when an article written by a well known mining engineer appeared stating that he and this prospector had been frozen in away north without an outfit, he having broken his leg and so being unable to travel. He further reported that on account of this prospector's woodcraft they had lived comfortably and well, and outside of being tied up with his broken leg, he had suffered no hardship.

The Chief had said to me, "Ambish, I don't think the people are getting this woods stuff right, and we are largely to blame. We have been publishing articles written mostly by amateurs and the dominant note is hardship, and then more hardship. Now you get right up North and trail this Hudson's Bay Bill and get the story right." So with a letter of credit on any of the Posts of the Hudson's Bay Company and the information that my man was last seen at a little jumping-off place Mus-keg-go-ga-ma on the Canadian National, he starts me off on this expedition—in the middle of January. To tell you the truth, I'm beginning to feel that my story, if I ever get it, will also be one of hardship and grief.

Well, I get to this Mus-keg-go-ga-ma place and everybody seems to be related to Pocohontas. I ask one of them if he has ever heard tell of Hudson's Bay, Bill and in strong Scotch he answers, "Sure. That's him over there at the Post getting ready to pull out with his huskies. I guess he's going back to his camp across the lake. The trail passes here, and as he swings down you'll get a chance to talk to him." As he pulls along side I halt him, introduce myself and tell him why I have come North.

"Come on over to the camp," he tells me, "and talk things over. It's just across the lake."

Pretty soon we come in sight of a well-built log camp facing the south and commanding a good view of the lake. In about two shakes Bill has his huskies tied up, a cheerful fire going, the kettle singing and is cooking some supper. Though he has only spoken a few words, by his actions he has made me feel like a long-lost brother. He has insisted upon my taking my boots off and slipping on a pair of beaded moccasins, and has got me planted in his home-made Morris chair. He tells me, "You'll camp here with me tonight and tell me your troubles."

While Bill is setting the table I sit back and take a few mental pictures of Bill and his camp. Everything

has been scrubbed white, and there are even curtains on the windows, and it is easy to see Bill has the artistic touch, the way he has worked birch bark into articles both for use and ornament. I see a couple of single beds both with red Hudson's Bay blankets and a caribou skin at the foot of each. But what strikes me most is a home-made book-case filled with the old masters, works on Geology and reports of the Departments of Mines. Then I take a look at Bill himself, built like Georges Carpentier, just as clean-cut, and unmistakably a natural-born athlete. In his khaki army breeches and his beaded moccasins he sure is a husky looking fellow.

While some of my pre-conceived ideas of a woodsman are undergoing some change, I hear him call me. "How would you like to join me with some of this Hudson's Bay Mixture?" motioning to his cooking which is already on the table. "Set right in while it's hot. You must be hungry."

While we are both doing justice to it, the newspaper man gets the best of me, and I go fishing for news.

"You've gone to a lot of trouble getting fixed up so comfy. You must expect to be here for some time."

"Yes," he comes back at me. "This is a big country I'm working in and it may take me years to work it out; so I'm making this my headquarters. I find it necessary to come out once in a while for my mail and supplies and this Mus-keg-go-ga-ma is the most convenient place. That's what has brought me out here now. I figured that the Department of Mines would be sending out some reports about this time to us prospectors who are on the mailing list."

"Then you are a prospector?"

"Yes, sir, and proud of it."

"Well, if it's a fair question," I ask, "why so proud of it?"

"Because it's my firm belief that at this particular time, the prospector who is really in love with his work can be of more service to Canada than in any other line of endeavor and at the same time, live a more ideal existence, and he has a good chance of being well rewarded for his efforts."

"But what about hardships, Bill? The prevailing idea outside is that this woods life is one continual round of hardships."

"Well," says Bill, "if you change that word hardships to pleasure, then you've got it right. Why, I'm getting twelve months in the year of what those people who are considered successful and fortunate only get two or three weeks in August—a trip in the woods canoeing and camping."

"Well, Bill, you are the first man I've ever read about or heard talk that way. But tell me, how did you learn to enjoy camping out in the snow, and it

ifty below?" This was a saucy one, but I'll blame that on my newspaper training.)

"I'll tell you," says Bill. "I learnt that from the man who has been camping all over America for ages—the noble Redman."

I could see that this prospector had a good story to tell, but I was in danger of losing it if I continued along these lines; so I decided to come right out in the open and declare myself, man to man.

"Bill," I began, "you have a good story to tell, and I'm going to ask you as one man to another to tell it to me because I'm convinced that it will do a lot of good. As I told you, our paper is at the present time carrying on a campaign, doing the best it can to enlighten the people outside about the actual conditions of frontier life, and your story, I feel, will not only be interesting but also an important contributing factor. So I ask you to open up and give the other fellow the benefit of your woods experience."

"Well," says Bill, "I like to hear a man talk that way; but in telling you the story, I'll have to go away back so you will understand the better how I gained that knowledge of woodcraft that has made life in the woods and prospecting for a living the only life for me. And if by telling this story it should be the means of bringing into the North some of your young men, who, I understand, can be well spared from the cities, to devote themselves to building up the Mining Industry and playing the Big Game, man fashion—well then I'll tell it with pleasure."

"You may wonder why they call me 'Hudson's Bay Bill.' To tell you the truth, as far as I know that's the only name I've got. If I had any other I lost it in France. This is what they told me when I came to in a German hospital—my mind a blank as to who I was or where I came from. Two machines, one a British, the other German, were seen battling away over the lines and had shot each other down. The German, Count Richoff, their ace, was dead and I was next door to it. There was nothing to identify me and the way I felt, I gave them no encouragement."

"I'll jump over the rest of my experience in Germany—it isn't pleasant—and I find myself in London, the war over, and myself in a bad state of mind. I don't know whether I'm a John Bull, Anzac, or Canadian. I can't recollect any thing previous to that crash. While I'm walking the streets of London I see a sign, 'Young men wanted by the Hudson's Bay Company for Service in Canada.' I offer my services and when they ask me my name I have to tell them what has happened. 'Well,' says the manager, who is a kindly sort, 'we'll give you a name—Hudson's Bay Bill—and we'll send you to a Post where you will have a chance to gather yourself together, and maybe, who knows, out there in the silent places it may all come back to you.'

"Sure enough they sent me to a quiet Post away inland, Conjuror's House Post, where I find myself in a new world and amongst the Hudson's Bay Scotch (half breed Indians) whom I soon learn to be real men. The nearest Post to us, Fort Missinabi, is a hundred miles away and they, like ourselves and for that matter most of the Posts of the company, are worlds unto themselves. The fur trade is the Big Business of the company, the winter occupied with hunting and trapping and after the Bear Hunt in the Spring, when all the hunters are in and the furs all well packed, then the 'Voyaging' begins, which means canoeing the furs down to the Bay, where the company's ship from England makes her annual visit,

bringing in supplies and the mails for the different Posts and gathering up a cargo of furs for the return trip.

"This trip down to the Bay is the big event. We usually spend a few days visiting, before starting back up-stream with our winter's supplies.

"I hadn't been long in the fur trade before I began to take an interest in life. My work in the winter was mostly travelling in company with a half-breed Indian named Donald McKenzie, gathering in furs, and in the summertime paddling down and paddling up some pretty rough rivers in company with these half-breeds and Indians with whom it was a treat to travel and to see the way they handled canoes in rough water. I can assure you I had a good chance to learn how to get around both summer and winter.

"Night after night during the winter Donald McKenzie and I would camp outside with only our 'pukwan' (toboggan cover) which we used for our lean to, a rabbit skin blanket and our camp fire; and we'd enjoy ourselves, roll out in the morning, wash in the snow, boil a couple of partridge, some caribou or moose meat and drink the broth instead of tea, pull down our pukwan, throw it over our toboggan and with our outfit laced up tight, maybe each drawing a toboggan, take turns breaking trail in the soft snow. As dogs would be of no use we had left them back at the Post.

"If our rations should happen to run out, we could most always get a bunch of partridge, even without a gun. We would 'shoo' them up into the trees where they would most always perch low; then we would cut a long slender tamarac like a child's fishing pole and with a buckskin string noosed and looped over the end we would slowly reach up and hold the noose in front of his beak, and sure enough he would stick his head into the noose; an upward jerk and it was all the same as fishing. Or if the partridge failed us we would take a fresh rabbit track and we would soon come to where Mr. Rabbit was 'setting.' We always had three ways of getting him into the pot—chase him under a brush pile and then set a couple of small traps for him (which we usually carried in case we ran across fresh fisher tracks, when we would run the fisher into a hole and get him the same way); or we would throw the tomahawk at him (the rabbit), or set a couple of snares ahead on his run-way. When a man has been drawing a toboggan or breaking trail in deep, soft snow and his guts have quit rumbling in disgust, it is surprising what little sporting chance the animals are given to make their get-away.

"But don't think this is hardship; this is the spice of life. I have yet to hear these people tell stories of hardship. There is always some way of getting by. Of course accidents will happen and if it should happen that you can't make a killing, your real woodsman is pretty much like a husky dog—good for a couple of days of fasting, which will most likely take him to some hunter's camp or his own.

"To cut a long story short the worst we have to contend with in the North is the North Wind, and the slush that always comes up on the ice after a heavy fall of snow. But they are both simple when you understand their little ways. The North Wind is the worst of the two; but he has been awfully kind to the movie people; he has supplied them with most of their chilly thrills. His sharp, biting teeth have no terrors for your Hudson's Bay Scotsman. Even though a

'Chinook' were coming over, he would take his teapail, axe, a few matches, and his sash and with his pukwan the North Wind could do his damndest. The Redman or those who have been lucky enough to learn his methods can buck him and get by. We often buck him and get by. We often buck him, but we do it very respectfully, because we know what he can do to us if we give him half a chance. If we are going to buck him, this is the way we do it.

"Maybe you've been setting traps or overhauling them alone. It has been soft all day, your moccasins and mitts are wet and maybe the snow has been sifting down between your pack and your back and the heat of your body has melted it. It is now evening, and that's the time the wind changes or rises, about sunset. You have a lake or two between you and your camp. Sure enough, the clouds that have been dangling low all day begin to lift, and are swinging around to the west and are soon coming from the North. The sky is now clear; the stars come out, and by this time your snowshoe thongs, mitts and moccasins are frozen stiff. You come out of the protection of the woods onto the lake, and that North Wind hits you and makes you feel like you have nothing on but a bathing suit.

"What are you going to do? There are just two things that the woodsman will do, and in either case he goes back into the shelter of the woods or behind the point. He shovels the snow off the side-hill with his snowshoe, pulls off some birch-bark, cuts down a dry stub of a pine or tamarac, makes a good fire, lays down some balsam or spruce brush below his fire to escape the smoke, dries well his mitts and moccasins, his snowshoe thongs and his top shirt or mackinaw. When he has put on everything good and dry, he takes that long woollen sash, winds it first round his head, next turn around his kidneys, and now out and around his waist, and with a little of that hot tea that is now boiled, he'll buck that North Wind and beat him, and will enjoy the satisfaction of knowing that he can beat him.

"Now let's see what happens to the Game Guy (that's when we are the gamest—when we don't know what we are up against). We left him just coming from the shelter of the woods onto the lake. The North Wind hits him and he feels like he's got nothing on him, no more than a bathing suit; his mitts, moccasins and snowshoe thongs are frozen stiff, but he sees a picture of his camp only a couple of miles away. Maybe his pardner is already there, with a fire on and the supper cooked. He is hungry. 'Oh, hell! I can make it,' (he is a game guy), and before he gets half way across he has provided good material for the movies or a first-class story of hardship.

"Now Mr. Newspaper Man I hope you get this idea right about hardship, and see how it can be turned into enjoyment and satisfaction. I can assure you it is some satisfaction to know that when the North challenges you, you can give battle and win."

"What about the summer, Bill?"

"The summer," he answers, "is one grand series of picnics."

"Picnics! For the love of Pete—you're forgetting the black flies and mosquitoes, Bill."

"We have no occasion to remember," he answers, "because the way we handle them they give us no worry. At night we have our little home made canopy, which is also a protection from a light rain, and

in the daytime, travelling or working, we use pine tar and sweet oil, mixed up with a little philosophy, which is surely efficacious. No, neither the mosquitoes nor black flies have any terrors when you've got the right outfit.

"Now, I presume, you want to know how I broke into the mining game. It was in the middle of the summer. We had just got back from 'Moose' (mouth of the Moose River), voyaging a load of supplies, when a Geological Survey party came in from the South. These were the first white people I had met from that side of Canada. They camped at the Post for a few days while they were examining some rock exposures in the vicinity, and young Carlisle told me about this country down here, how the country was getting opened up, and what a great work the prospectors were doing in blazing the way, and what a fine free independent life they led. He spoke also of the opportunities there were to make a Big Strike, which would not only benefit me but the other fellow as well. When I told him later I had decided to go down there, he advised me what books to get on Geology and Mineralogy and what government reports, and in fact got me off to a good start.

"As soon as my period of service was up with the H. B. Co., instead of going back to the Old Country, I came down here, made a trip through the different mining camps, was courteously shown round, had things explained to me and came away from the mining camps with an outfit and a pretty fair working knowledge of where I was going. I chose this part of the country to work in after convincing myself that both the Porcupine and Kirkland Lake gold belts cross this Canadian National Railway to the west.

"This part of the country needs prospectors bad, and there is really a good opportunity for the fellow who will apply himself to work and study. I can see that this prospecting is becoming fashionable as a profession; so when you get back to the city and see any young fellows of the right cast, you might tell them that the land of opportunity is challenging them."

"Well, Bill, after listening to that story of yours, I'll take up that challenge myself, and, I feel I'm going to win. Let's shake!"

## POSITION OPEN IN BRITAIN

The following cable received last week by the Deputy Minister of Mines, Ottawa, shows a first-class opening for a mining engineer proficient in coal mining. Further information can be had on application to the Deputy Minister at Ottawa.

London, March 17th.

"Deputy Minister of Mines, Ottawa.

"Secretary, Mines Department, London, invites applications for post under Safety Mines Research Board. Appointment whole time one, with superannuation. Salary dependent upon qualifications, but not exceeding two thousand pounds per annum. High general scientific qualifications and experience in engineering required, also knowledge of coal mining. Holder of appointment advises Board on research questions relative to safety problems in coal mining and coördinates Board's scientific work. Closing date April Thirtieth. Writing."

"Dominion".

## British Institution of Mining And Metallurgy

Meeting in London Discusses Liquid Oxygen Explosive and the Aneroid Barometer

By ROLAND H. BRIGGS

At a meeting of the Institution of Mining and Metallurgy held in London, England, on February 15th, 1923, papers were read by Mr. Alfred James on "Liquid Oxygen in Mining", and by Mr. R. H. L. Lee on the "Aneroid Barometer and Barograph in Engineering". Mr. James explained that it is now 20 years since the use of liquid oxygen was advocated in mining, and its success during the driving of the Simplon Tunnel caused much favourable comment. The use of the new explosive was greatly increased during the war, owing to the shortage of glycerine. By 1917 the use of liquid oxygen had become general in Germany, by which time there were 72 plants in use at coal mines, varying in production from 5 litres to 110 litres per hour; 56 plants in use at metal (mainly iron ore) mines, ranging from 7 litres to 265 litres per hour capacity; and 32 plants at potash mines. The consumption for explosive purposes in Germany alone was said to have reached during the year 1917, about 23,000,000 litres of liquid oxygen per annum.

### Liquid Oxygen Explosive in Mexico

It is stated that  $1\frac{1}{2}$  litres is as efficient as 1 kilogram of dynamite, though in practice the proportion may be increased to 2 to 1 to allow for evaporation and for the excess of oxygen always desirable in blasting operations. Since the war many users have reverted to the more easily obtainable gelignite, but some large mines still obtain their output by the use of liquid oxygen, notably the de Wendel Mines in Lorraine. The most interesting information at the moment, however, is the remarkable results obtained by Messrs. Calland & Kuryla at the Real del Monte Mines at Pachuca, Mexico, with this method of blasting.

The Rozario mine of this large group has been for the last year maintaining an output of 450 tons per day by the use of liquid oxygen, at an expense of only 65 per cent. of the cost of dynamite at 12 cents per lb. The liquid oxygen is made on the spot by compression and cooling of the atmospheric air, the nitrogen in the liquid air produced being eliminated by differential distillation. The oxygen is drawn off at intervals from a sump into flasks on the thermos principle. Air is first drawn through a tower, through which caustic solution is passed, to separate out the carbon dioxide, after which the air passes into a compressor to bring it to sea level compression.

From the atmospheric compressor the air passes into a 3-stage compressor delivering its output at 3,000 lbs. per square inch. This passes through oil and moisture separators to a nitrogen air cooler, after which more oil and moisture are extracted. The air is then rewarmed, passes through a dryer and next to an ammonia air cooler, whence it passes to an air liquifier. In this apparatus the highly-compressed air passes through long, thin coils surrounded by nitrogen gas, at about -190 deg. C., which has distilled from the liquid air condensing at the bottom of the liquifier. Liquid nitrogen boils at -196 deg. C., liquid oxygen at -184

deg. C. By maintaining the temperature at -190 deg. C., the nitrogen is not liquified, but passes off round the coils, thus cooling them to the temperature required for the liquifaction of the oxygen only. The plant at this mine produces 27 litres of liquid oxygen per hour at a low cost.

### Method of Using Liquid Oxygen

The liquid oxygen is conveyed to the mine in the thermos flasks, and is poured at the actual firing place into vase-shaped containers holding six carbon cartridges. The latter remain immersed for five or ten minutes, and are then inserted in the drilled holes. Electric firing was at first used, but was subsequently replaced by the ordinary fuse and detonators. The blasting is good, the rock being well shattered and the percentage of misfires low. Eighteen or more holes can be fired at one time, the limiting factor being the evaporation of the oxygen. The cartridges are of lamp black in paper containers, and the normal 35 mm. cartridge retains the oxygen in excess for 14 minutes. Sawdust cartridges are only useful for 3 or 4 minutes. The cartridge must absorb more oxygen than the chemical equivalent needed for the reaction, so that carbon dioxide, and not carbon monoxide, is formed. The absence of fumes, easy and quick access after firing, coolness of the atmosphere, innocuousness of "missed" holes after fifteen minutes, all appeal to the miners.

The strength and shattering quality of the explosive may be varied as desired within limits, the blasting is carried out by ordinary miners, and the liquifying plant is run by men without special experience; but the great success of the plant is undoubtedly due to the technical skill available. The results are very satisfactory where cheap power is available, and where imported dynamite is expensive. In "reef" mines there are usually a few holes inaccessible to liquid oxygen containers and for these gelignite is still used.

### European Practice

Contrasted with the Pachuca practice, European methods tend to the replacement of soot cartridges by those containing little carbon. These give greater shattering power and a clearer atmosphere, with little carbonic oxide. Detonators are not used, the notched end of the fuse without a cap being inserted into the cartridge and the fuse fired in the ordinary way. Blasting takes place under water as freely as in dry holes. Cartridges are made of permeable mine dust or grit well rammed in by means of a wooden rammer. The fact that detonators are not used makes European practice less costly and the atmosphere less toxic. The cartridges have a time limit of 30 minutes, the greater period being partly due to the slightly larger diameter, 38 mm. At the great tunnel of the Rove, (Marseilles), the results show liquid oxygen to be 3.6 times cheaper than dynamite for underground work and 4.39 times cheaper in the quarrying work. At Uckange (Moselle) they find that 1.13 litres of liquid oxygen equal 1 kilogram of black powder. At the iron mines of Lorraine, where about 7,000,000 tons of iron ore are produced

yearly by means of liquid oxygen, very high economies are claimed. But it must be remembered that the success of a liquid air installation is mainly dependent on the quality of the technical supervision available.

There is a great reduction of accidents reported in the European mines extensively using liquid oxygen. The output per litre may be judged from the facts that in one group of mines in Lorraine there is an output of 12,000 tons per day for a production of 220 litres and an actual consumption of 150 litres per hour, and at another mine 260 tons are produced for an actual consumption of 2.5 litres per hour. In Mexico, 27 litres per hour suffices for an output of 450 tons per day, and in addition supplies the oxygen necessary for welding and cutting in a large engineering works. The calories generated by the explosion of liquid oxygen are greater than with gelignite of the highest grade, and liquid oxygen is one of the most powerful explosives capable of use in mines.

An installation producing 30 litres per hour requires 30 ft. by 50 ft. of floor-space and about 74 horse-power. A 75-litres per hour plant would require 135 horse-power. Modern installations are much more efficient than the earlier models. The atmosphere in an underground stope after a blast tends to the exhilaration of the worker, rather than the reverse. It is claimed that the presence of liquid oxygen has a similar effect on the mine atmosphere to that of ventilating and refrigerating plants. The use of gaseous oxygen in rescue apparatus for mines is well known.

#### Precision of Aneroid Barometers

Mr. R. H. L. Lee, in the second paper, described the uses of the aneroid barometer in practical engineering. The aneroid is simply a delicate spring balance in equilibrium, which measures differences of atmospheric pressure with a great degree of accuracy. As difference in altitude is not directly proportional to difference in pressure, where the pressure scale of the aneroid is divided into equal divisions the altitude scale is divided into gradually decreasing divisions as the height increases. Or the aneroid dial may have an equally divided altitude scale, with an unequally divided pressure scale. The former type is called an "orometric" aneroid, the latter type an "altimetric" aneroid. In the altimetric aneroid the altitude scale may be fixed or may revolve round the aneroid, so that its zero coincides with the hand, wherever it may be.

The aneroid was invented by a Frenchman in 1843, and the first altitude scales were added by an Englishman in 1851. The limitations of the instrument and complications of atmospheric pressures prevent it from competing with direct measurement, but it has a wide practical scope for rapid determinations of considerable differences of level. No aneroids should be considered which do not carry the certificate of the National Physical Laboratory or equal.

The limits allowed by the National Physical Laboratory for 5-inch diameter aneroids are a maximum scale-error not exceeding 0.04 inch of mercury, or about 40 feet of altitude in a 5,000-foot range instrument, while the average difference between the errors in ascending and descending must not exceed 0.03 inch, or 30 feet. In good aneroids the average maximum error varies between 20 feet and 30 feet. Such errors are very small when measuring comparatively large differences of altitude, but they illustrate the limitations of the aneroid in measuring small differences.

In the case of a 15,000 feet range instrument, the limits allowed are 0.13 inch, or about 130 feet maximum scale error, and an average difference of 0.27 inch, or about 270 feet between rising and falling. Increasing the range to 15,000 feet involves a much greater allowance for error, so that it is inadvisable to purchase such an aneroid for measuring heights less than 5000 feet. The above limits are being improved upon, and altimeters reading to 20,000 feet can be guaranteed within 100 feet error at any point. The tendency is to reduce the National Physical Laboratory tolerances and it is always possible to stipulate for extremely accurate instruments.

The barograph is an instrument that automatically makes a graph of variations in atmospheric pressure against time. In taking altitudes with an aneroid a barograph is a ready means of obtaining automatically a continuous record of atmospheric pressure changes under the best conditions. Good records can be read 0.01 inch, or 10 feet of altitude, which is quite satisfactory for correcting survey records.

#### THE SCHREIBER FIND

The following report of the operations of Messrs. Foster and Glendenning on Schreiber Point appears in this week's "Financial Post.":

Actual tests of ore taken from the new find at Schreiber show values running around \$250. The find in question was made by Messrs. Foster and Glendenning. Assays showed what were termed wild values. Some of them ran into four figures. A test shipment was prepared and sent to the Temiskaming Testing Laboratories at Cobalt. Charles Randall was engaged to conduct tests on the ore. Results have been startling.

Six bags of ore were sent along for the test. Two were estimated to contain \$100 ore and the other three \$250 ore. Mr. Randall pooled the lot and then subjected samples to 36-hour treatment, employing the following methods and getting the following result:

|                               |     |
|-------------------------------|-----|
| Straight Cyanide, roasted ore | 76% |
| Straight Cyanide, raw ore     | 94% |
| Bromo Cyanide, roasted ore    | 95% |
| Bromo Cyanide, raw ore        | 98% |

Ore heads ran \$250.

Then the test was carried on for 50 hours with the following result:

|                               |          |
|-------------------------------|----------|
| Straight Cyanide, roasted ore | 79 %     |
| Straight Cyanide, raw ore     | 98 2/10% |
| Bromo Cyanide, roasted ore    | 97 8/10% |
| Bromo Cyanide, raw ore        | 99 1/10% |

Ore heads ran \$258.60.

These tests are not final. Mr. Randall is continuing his tests. He believes that with fine grinding and long treatment in straight cyanide solution he will be able to get an extraction of 99 1/2 per cent.

To enable further tests to be carried on a 20-ton shipment of the ore is now on its way to Cobalt. This is taken from a large high-grade vein which has been traced from the shore of Lake Superior up the side of a large cliff for some distance and has also been located over the summit of the cliff. But little sinking has been carried out as yet, the work done going down but 15 or 20 feet.

The find in question was the result of prospecting undertaken on the recommendation of one of the Provincial Geologists who had been over the section and encountered the promising geological conditions.

# London and Canadian Mineral Resources

The Keeley Mines, Dr. J. Mackintosh, Bell, and a Complimentary Dinner

By ALEXANDER GRAY

On Monday, 19th, at the Piccadilly Hotel, London, the dinner went round with the viands and with the courtesies turned upon Canada and its mineral resources. The occasion was a complimentary dinner given by Mr. Fred H. Hamilton and the Directors of the Hamilton Bell Company, Limited, to their Canadian Consulting Engineer, Dr. J. Mackintosh Bell, M.I.M.M. Mr. Hamilton B. Wills, President of the Vipond Company and incoming President of the Keeley Company, being included in the toast of the evening. Mr. Hamilton was at his best as toastmaster, was felicitous in his tribute to Lt.-Col. Bell, for his ~~documental services~~ *documental services* in Russia, Australasia, Flanders and Canada, and incidentally complimented Mr. Wills for his exceptionally intimate knowledge of the mines of Canada.

Coming from a gentleman of Mr. Hamilton's erudition — learned as he is in literature, the arts and mining finance, a rare combination — all that was said about Canada and its personalities, and the Keeley Mine in particular, was apt, most cordial and optimistic. No shadow could be thrown "across the pale parabola of joy," between the soup and nuts (quoting the euphonious if abstruse poet) where there was conviviality and enthusiasm directly attributable to developments at the Keeley Mine, of which Dr. Bell had this by way of narrative:

## Pre-Cambrian Potentialities

"He said it was perfectly true that from his earliest acquaintance with Mr. Hamilton he (the speaker) had perceived the possibilities of Canada. Mention had been made of the great mineral wealth that had already been unearthed in those rocks which, following British usage, they had called archæan, but which Mr. Hamilton more correctly called pre-Cambrian. It was a huge triangle stretching from Michigan, to Wisconsin, south of Lake Superior, extending northwards almost to the mouth of the Mackenzie River, an area of country equal almost to half the territory of Canada, which possessed huge mineral possibilities. He did not think he was going too far when he emphasised what Mr. Hamilton had said, that if they looked over the records of mineral advance within the last 30 years, they would find that by far the greater proportion of the mineral discoveries of the world had been made in very small portions of immense tracks of country. Not only did the iron and copper deposits of Michigan occur there, but the deposits of Sudbury, Cobalt, Kirkland Lake and other districts. Wherever the pre-Cambrian rocks occurred mineral was to be found, and it was really extraordinary how widespread were the deposits, which seemed to present great potentialities. It was a delightful thing for them, as Britishers, to realise that they had this within the Empire. Not only were there great possibilities in the unknown country — because it was only a few stretches that had been explored, and those lying near the railways — but even within such areas as Cobalt or Porcupine itself, which were, relatively speaking, well known, there were possibilities which presented great attraction.

## History of the Keeley Mine

"The Keeley was one of those. It was discovered in the autumn of 1907, and the Keeley mine was shortly afterwards bought by a gentleman associated with an organisation known as the Farmers' Bank. The bank advanced large sums of money. The purchase price of the property was \$350,000. An immense amount of machinery was installed, and buildings, etc., erected to develop an extremely rich but, as it turned out, very small deposit on the surface. Within a year and a-half the mine had closed down and the Farmers' Bank, who had been its sponsors, had come to grief. Needless to say, when he got there, a few years later, the camp was as dead as it could be. But there were certain structural reasons which suggested the possibility of those bonanzas they were now encountering, and it was for that reason he took it up. It required a tremendous amount of financial courage, however, to back a purely geological hypothesis — because that was all it was. There was not an ounce of silver showing. Although he appreciated the very kind remarks made by Mr. Hamilton, he could not forget the backing he had always had from him, and from Mr. McCarthy in the technical sense.

"Mr. Hamilton had paid several visits to Canada, and it had been a great inspiration and help to have him there. The day before he (the speaker) left Canada the most remarkable discovery that had ever been made was made—what they called the 'Birth-day Bonanza' was found. He had never seen anything quite so extraordinary in his life—ore averaging 7,390 ozs and 4½ ft. in width. (Applause.) He could not tell them what a great pleasure it was for him to feel that he had been instrumental in some small way in a British company 'making good' in Canada. (Applause.)"

## Appreciation of Dr. Bell's Work

A bumper crop of silver raised upon the ruin of the Keeley property, was a theme to evoke the applause that greeted Dr. Bell. To have a geological hypothesis fructify after so many years into a be-silvered phenomenon, with ore of almost incomparable richness, lent substance, charm and gayety to the festal board, and was ample incentive to form the basis of Mr. Hamilton's remarks, which were more than congratulatory to Dr. Bell. He reviewed his acquaintance with Dr. Bell, from the time he returned from New Zealand, twelve years ago, where he had been Director of the Geological Survey, until the present. During that time he had been associated with a London financial group and recently had brought to their attention the Vipond property, adjoining the Hollinger, and the Keeley in South Lorrain. Of the Keeley Mr. Hamilton said that "even in the palmy days of Cobalt there was no one mine that could show so much high-grade silver ore at any one time as the Keeley could show today." For the Vipond Mr. Hamilton had rosy prognostications to offer.

## Canada a Truly Remarkable Country

Breaking bullion by the ton in the manner outlined by Mr. Hamilton at the Keeley, of which the Wett-

laufer is alleged to have been a mere offshoot, is more concrete than the proposal made in the early days when Mr. Wills was moving the Watts, to "reduce the ore directly to a matte," and thereby simplify metallurgy that bothered Cobalt producers not a little. Mr. Wills, in those days, was an adept novice. He planned revolutionary practice. To-day Mr. Hamilton recognizes him as an outstanding authority on mining affairs throughout the Northland; and the Keeley, the ugly duckling of its discovery period, has all the radiance of the fairest and finest, to be a source of pride and profits, miningwise and marketwise, when the essential details are arranged and production is what is anticipated. Mr. Hamilton and Mr. Hamilton B. Wills know how. Of course, it may not be that the Keeley has as much high-grade silver in sight as any one mine at Cobalt had in its palmy days. South Lorrain has vagaries! But if what the company has is the entrée — if the roast has yet to be served — the meal will be Lucullian and not at all enervating. Mr. Hamilton breathed over the banquet the spirit of the new era when he reinforced Dr. Bell's deduction that "Canada was a remarkable country." Quoting a well-known authority, he reached the conclusion, now known to every Canadian who reads any newspaper, that if the little triangle of pre-Cambrian rocks that juts into the United States south of Lake Superior contains such riches as it does, Canada's vast areas of the same rocks will disclose mineral wealth of which the present mines are the merest sample.

#### Where Canada Leads — London Should Follow

Of special interest at this moment, when the attention of London is sought and when such men as Mr. Hamilton, Dr. Bell and Mr. Curle have spoken, was the brilliant horoscope drawn by Mr. Hamilton with reference to Canadian opportunities. No one is better qualified to fresco facts. South Africa knew him as a forceful personality. He and his colleagues have operated in Australasia, South Africa, Russia and elsewhere. Without abandoning his affection for those fields, but with all the fervor born of South Lorrain values and widths, Mr. Hamilton in his best style put Canada in the picture, when he said:

"He wanted to put it to them that night that London, which was the centre, and had been the centre for a generation, of the mining markets of the world, could not afford to ignore those great developments. He did not think it could ever have afforded it less than to-day, because, owing to the energies of advanced politicians in Russia and elsewhere, a great many large and rich areas of the earth's surface which had been open to British enterprise were now no longer so, and he thought they could only continue to ignore them by allowing that condition of leadership to pass not to Toronto but to New York, for it was remarkable that America had profited more largely than any other country. On national grounds alone, he ventured to say it was undesirable, with this great development which was going on, and which was increasing in importance every year and almost every month, that American capital should over-shadow British capital.

"Personally, he believed that they were on the eve of a very considerable development, and that before many years were over they would see a long list of Canadian Mining stocks dealt in with equal facility in London and in Toronto. (Hear, hear.) There were

technical difficulties in the way, as gentlemen of the Stock Exchange knew, but they were in process of solving them. It might be delayed by 'wild cat' promotions, but that it would come he felt confident, because it was based upon the unassailable foundations of enormous natural wealth which only required systematic exploration and development. (Applause.) He appealed to them, on economic grounds, on national grounds, and on the narrow, but not irrelevant, ground that it was calculated to replenish the deserving institution, the Stock Exchange, and many others — (laughter) — that this movement was deserving of their sympathy and support. He was very glad to feel that it had been powerfully assisted by the achievement of their friend, Dr. Bell, whose health he was now going to ask them to drink. He also coupled with the toast the name of Mr. Wills, the president of the Vipond, and who would shortly become president of the Keeley. He probably knew the mines of the north as well as any man in Canada, and was, he (the chairman) was sure, equally convinced that the co-operation of British and Canadian capital was calculated to be fruitful and beneficial to all concerned." (Applause.)

#### Our Metallurgical Methods Ahead

That Mr. Hamilton has a sootherin' way with him more effective than "that rogue Reilly", will be readily acknowledged. Mr. Wills made the fine point that Northern Ontario has "the largest mining industry in any one Province in the world," which is perfectly true, because the Transvaal is a Colony and mineral production over the border is reckoned by States. It remained for Harry S. Denny, C.B.E., M. I.M.M., erips as a new "tenner", competent in his sphere as a Metallurgical Engineer, captious to the point of caustic criticism when he has the urge, to propose the toast to Chairman Hamilton and to lend the weight of his personal opinion as a Scientist, that Canada has a lot of things worth having. Mr. Denny filmed the results of his recent visit to the North Country. He said his visit to the mines of Porcupine, Kirkland Lake and Cobalt had left him impressed particularly by the metallurgical efficiency attained. He was pleased "to find that in metallurgical methods they had eaten the Witwatersrand . . . The Wright-Hargraves has one of the prettiest plants in Kirkland Lake. . . They were crushing 250 tons of rock per day and they told me that the full complement of men on the plant was two or three. The remarks that have been made about the possibilities of Ontario are, so far as I have been able to observe, very accurate. I came away impressed with the profound conviction that there is an immense future for Ontario."

#### Cigars, Coffee and Dividend

Concluding with the comments of the Agent-General for Ontario, a response by the Chairman, the usual afterthought to the "Press," the cigars and coffee, it devolved upon Dr. Bell, upon his return to Canada, to announce the declaration of an interim dividend on the Keeley shares of 8 per cent. on the \$2,000,000 capital. All the shares having been issued, the amount involved in the distribution is \$160,000. Evidently there was a recent issue of 700,000 treasury shares, which was to be expected in view of the mining and market prospects.

## WESTERN CHEMICAL INDUSTRIES

(Prepared under the Direction of Dr. Charles Camsell, Deputy Minister of Mines by Dr. A. W. G. Wilson, Chief Engineer, Mineral Resources Division.)

The Prairie Provinces of Canada are classed primarily as agricultural areas and up to the present time they have not been considered seriously as probable contributors to the mineral wealth of the country. Recently, however, the resources of these provinces in non-metallie minerals, such as clays, coals, oil, gas, and the sodium and magnesium salts, which occur in the numerous alkali lakes and sloughs throughout the area, have been attracting the attention of capital with the result that considerable activity is evidenced in all these lines.

The increased interest in the alkali deposits of Western Canada has induced the Mines Branch of the Department of Mines, Ottawa, to institute a detailed investigation of these deposits with a view to determining their possible economic value and the extent of resources. The work has now been in progress under the direction of Mr. L. H. Cole during the last two field seasons.

Natural occurrences of soluble mineral salts are known in the provinces of Manitoba, Saskatchewan, Alberta, and British Columbia, either in the form of bedded deposits or as brines. Some are of considerable extent and are probably of sufficient size to warrant commercial exploitation, provided economical methods

of recovery can be developed and sufficient markets can be established.

Three of these deposits are being operated or will shortly be operated in the Prairie Provinces and plans are under way for the development and operation of a fourth deposit.

At Dana, Saskatchewan, a half million dollar plant is nearing completion, to extract salt cake and other chemical products from the brines of Muskiki lake, formerly Houghton lake, 23 miles west of Humboldt, Sask. The company operating this deposit is The Salts and Chemicals, Ltd., controlled by Canadian and United States interests. The main plant of this company is at the deposit at the lake and they have a refining plant at Kitchener, Ontario. When this plant is in operation it is estimated that the output will be 30,000 tons of salt cake per year besides Epsom and other salts recovered as by-products. A small village has been erected at the lake with housing accommodation for 60 men. When the plant is working at fuller capacity 100 men are to be employed.

## Sodium Sulphate Plant

At Frederick lake, five miles southwest of Dunkirk, Sask., and 38 miles from Moose Jaw, Sask., another salt cake recovery plant has been erected by The Bishopie and Lent Co. with head offices at Cincinnati, Ohio. This plant is practically completed with a capacity of fifty tons of salt cake per day, and as soon as it proves commercially successful, further units

(The above cartoon has even greater significance now than when it was first printed in these pages three years ago.)

are to be added to increase the output to 200 tons per day. At the present time, twenty men are employed at this plant.

At a lake five miles north of Fusilier, Saskatchewan, an experimental plan has been operated by a company called Soda Deposits, Ltd., with head office at Calgary, Alberta. This deposit, although somewhat smaller than some of the other deposits, contains sodium sulphate in a very pure state and several shipments have already been made. This company hopes in the near future to be in a position to put its product regularly on the market.

In British Columbia, the Basque Chemical Co. is operating a series of five lakes situated fifteen miles west of Ashcroft, B.C. From these lakes they are excavating crude magnesium sulphate (Epsom salts) which is shipped to Vancouver where it is refined and sold as medical salt and to the tanning industry. Plans are now under way for greatly extending the development of this deposit.

In the vicinity of Meadow lake, fifty miles north of Clinton, B.C., the Lillooet Soda Co. is operating a sodium carbonate lake and shipping their product to Vancouver over the Pacific Great Britain Railway. This material is being disposed of at the present time to the soap manufacturers of the Pacific coast, but plans are under way to dry the material at the lake and increase the output.

#### The Main Products

The several main products which may be expected to be produced from these deposits are Glauber's salt, salt cake, Epsom salts, soda ash, and baking soda.

Sodium sulphate in the anhydrous form, more commonly known by its trade name of salt cake finds its chief use in the manufacture of sulphate pulp, in metallurgical work in the refining of nickel, in the manufacture of window, plate, and bottle glass, and in making water-glass. In the hydrous form, it is marketed as Glauber's salt, and as such is used in tanning, in the textile industry as a mordant, and in medicine.

Hydrous magnesium sulphate or Epsom salts is largely used in the cotton trade for warp-sizing; it is also employed for medicinal and agricultural purposes, and in dyeing with aniline colours, since goods thus treated are found to withstand the action of soap better than those not so treated.

Sodium carbonate in the anhydrous form, known under the trade name of soda ash, is one of the principal forms in which sodium salts are used in the alkali industry, since it frequently forms the base from which other sodium compounds are made. It is used extensively in the manufacture of glass, soap, and dyes, as well as in cleansing preparations, metallurgical processes, and tanning. In the hydrous form it is marketed under the trade name of salt, soda, washing soda or crystal carbonate and as such is used in softening water and to replace soda ash when purity is essential. Sodium bicarbonate or acid sodium carbonate, commonly known as baking soda, is generally marketed in a very pure form, and finds its principal use for making baking powders.

The operations of these companies tend to bring before the public the possibilities of the western provinces in the mineral field and should form the nucleus of the ever increasing industry which in time should prove of great importance to the whole of Canada.—From "Natural Resources."

## MINING OUTLOOK IN THE YUKON

Although in Ottawa, which is in constant touch with the outposts of the Dominion, information is always available, through the North West Territories and Yukon Branch of the Department of the Interior, of that most distant field, Yukon, the presence at the capital on official business of Mr. George P. MacKenzie, the Gold Commissioner, attracts to the territory and its affairs more than usual interest. Mr. Mackenzie is the chief executive officer of the Department of the Interior in the territory and is in touch with all its activities.

### Great Natural Resources

Yukon has great natural resources in her game and fur, and in recent years the agricultural development has been very marked. Fur farming is also becoming an important industry. These, however, are secondary or subsidiary to the metal mining industry which originally attracted the attention of the world to the territory, and which now shows every promise of renewed activity.

Yukon Territory is now a recognized producer of gold, silver, lead, and copper. The total output of the territory to date may conservatively be given as follows: Gold, \$200,000,000; silver, 3,500,000 ounces, valued at \$2,100,000; lead, 3,500 tons, valued at \$400,000; and copper, 12,000,000 pounds, valued at \$2,700,000.

The principal placer field, the area within fifty miles of Dawson, has been intensively operated during the past twenty-five years. The life of the camp during that time may be divided into three phases in so far as the methods employed to recover the gold are concerned: (1) "the primitive," covering the period of wood fires and small open cuts; (2) "the mechanical," when, although the operations were still conducted by individual operators, steam power was used operating certain types of machinery, the greater part of which was evolved in the territory to meet local conditions, and, (3) what may be termed "the corporation" period, which entailed the formation of holdings extensive enough to warrant a very considerable capital expenditure on account of plant, by means of which results could be obtained much more efficiently and much more economically.

While there are quite extensive areas within the Klondike and other districts where ground can still be profitably operated by individual effort, up-to-date mechanical methods being employed, their life as fields of individual endeavour is largely dependent upon the day when the larger plants become available. It may, therefore, be considered that the placer areas immediately surrounding Dawson have passed through the first two phases. A part of this field has also received its final clean-up under the third and last phase of mining activity, but there still remains an area which will keep the available plants, both dredging and hydraulicking, occupied for many years to come. It is not easy to forecast the life and gross results of these operations, but it is safe to say that they will continue for twenty years and should maintain or exceed the present annual output of something over one million dollars per year.

The copper areas of the Territory have not during the past year been active. This is due not only to the copper market but even more to the fact that these deposits have heretofore been operated entirely as "high grades," no capital expenditure which might

put them in the market as standard producers, having been made

### Silver-Lead Ores

Of the total silver output quoted above, over 2,000,000 ounces have been secured as a by-product in the refining of placer gold. During the year 1914-15, some 1,000 tons of silver-lead ores were shipped from the Mayo district. The property supplying this then stopped production and it was not until the discovery of new leads on Keno Hill in the same district that shipments were resumed. During 1921-22, about 5,000 tons of ore were shipped, yielding some 200 ounces per ton in silver and 60 per cent of lead.

During the coming season not less than 7,000 tons of ore of as good or better grade than the above will be produced. Up to the present, by far the greater part of the territorial income has been derived from placer gold operations, and while there is no reason why these should fall below their average of recent years, there is very little doubt that the silver-lead areas will shortly develop the more important industry.

### The Mayo District

The Mayo district now appears to have all the factors that are necessary to the development of a high grade silver camp. Already over 1,500 claims have been taken up, many of which show well defined outcroppings of silver lead ores. Upon three groups a considerable amount of development has been done and two of these are shipping high grade ore with every prospect of increasing their output to the capacity of the transportation systems. At present, the ore is hauled some forty miles, by either horses or gasoline tractors, to the bank of the Stewart river from which it is shipped by river and ocean boat via the mouth of the Yukon river, to Pacific coast smelters. Under present conditions the ore that can be successfully treated is slightly over \$100 per ton. This means that only the higher grades of ore can be handled at present, but the active properties are blocking out much milling ore which it is hoped to either concentrate and ship, or alternatively, reduce in a local smelter.

The camp is already served with good winter roads which can by a moderate expenditure be improved for summer use for all classes of traffic. The camp is easily accessible during summer by steamboat and during winter by stage from Whitehorse. The country affords sufficient lumber for general mining operations and it is also most fortunate in its power potentialities. Fraser falls on the Stewart river, the Canyon on Mayo river, and Janet creek, all quite close to the operating properties, can be developed to produce ample power for all purposes, including the electrical reduction of the ores. It is also feasible to use the power already developed on the Klondike. This could be done by the construction of something less than 100 miles of transmission lines.

The views of the residents of the territory and all those interested in its mineral resources and production are now most optimistic. The life of the placer fields is anything but over, and now it appears certain that a period during which the silver-lead areas of the territory will equal or exceed the gold fields in the production of wealth has just been entered upon, while further gold, silver, and copper deposits may be said to be held in reserve awaiting the day when the world market calls them.—From "Natural Resources."

## LUBRICATION OF GEARS

By CHESTER B. HAMILTON, Jr., M. E.  
President Hamilton Gear and Machine Co.

Durability of gears, given correct design, is dependent largely on lubrication. If an oil film could always be maintained between the teeth they would last indefinitely. This is dependent on two things,— 1 freedom from prolonged overloads which force an abrading metal to metal contact, and, 2. a supply of suitable lubricant to maintain the oil film. The oil must be heavy and sticky enough not to be thrown off nor be squeezed out from between the surfaces. It must be low enough in viscosity to flow freely to the parts needing its service.

### Heavy Oils

For fast running gears which are not enclosed it must be high enough in viscosity to bear the load and to remain on the gear in spite of the effect exerted by centrifugal force. For such applications asphaltum or bitumen base oils are excellent, and also for heavy coarse work such as rolling mill gears. A better lubricant where stickiness is not so essential, and one with almost as high viscosity is a steam refined transmission oil of about 1100 sec. (Saybolt) viscosity. This is the best type of oil for enclosed gear cases. It is better and also cheaper than the 600 steam cylinder oils commonly recommended. In cold weather it may be thinned with a light paraffin machine oil to the desired fluidity.

### Greases

Do not use cup greases of any kind for gears. It does not pay. Like the cylinder oil mentioned above, they are made for specific purposes and should be confined to them. Ball and roller bearings should be packed with petrolatum, vaselene or mineral jelly, which are different names for the same thing.

### Solid Lubricants

Graphite is an excellent solid lubricant. It can best be applied in repeated small doses mixed with the oil. It fills the pores or irregularities of the bearing surfaces and being solid does not squeeze out. Fibre greases should be avoided. Their sole purpose is to act as a cushion to quiet badly worn and noisy gears, and are bad for the bearings. A sufficiently heavy oil would be better.

### Metals

Lead is an excellent solid lubricant if provided in the alloy of worm gear metal. Up to three per cent may be used in bronze worm gears and ten per cent is standard for bronze bushings. For any pair of gears it is best to use different metals or metal of different hardness. This applies especially to soft steel but not to cast iron or to hardened steel which are exceptions to the rule.

### For Rawhide Pinions

It is generally best in this case not to use any lubricant, but if such is desired use only small quantities of a paste made of linseed oil and flake graphite. Avoid all other oils and greases, even those excellent belting oils, neatsfoot and castor oils. Rawhide pinions out of use may be protected from moisture by coating with hot paraffin wax or shellac.

### Gear Cases

For a heavy oil use steam refined transmission oil, but where the case oil is worked through a circulating

system or fed to ring oiling bearings a lighter oil is needed of about 300 sec. or more viscosity. Use a straight paraffin oil of the viscosity to suit the job. Gear cases should be provided with a drain plug from the lowest point, where sediment would lodge, and also high and low level test plugs, as well as an inspection hand hole.

#### Oil Level

The depth the gears dip into the oil bath is important. The level should never rise above the side of the rim for fast running gears. Worm gears should be arranged with the worm below and provided with a packing gland. Otherwise the maximum level will be governed by the escape of oil through the bearings.

#### AN ADJUSTABLE SHEET METAL HOLDER

Sheet metal can be stored in many ways; in racks vertical or horizontal, on suspended platforms, reared against a wall or just simply laid on the floor. The holder shown in the accompanying photo will, in many instances, be found much handier than others, however, because of its adjustable feature. When material of this kind is likely to remain in an undisturbed condition for some time it might with advantage be laid on the floor in some out-of-way part of the building, but otherwise it is much handier to have it on end and in a position easy to reach.

The adjustable holder shown here is a step in advance of the solid rail behind which sheets of copper, iron, brass etc. are often stored. A solid rail, of course, answers the purpose providing a sufficient number of sheets are stored behind it; but if the number is not sufficient to fill the space between the rail and the wall, the metal sheets work out in one way or another and become a nuisance. The rail shown in the illustration is loose and slides up or down in eye bolts screwed in the wall. Various numbers of sheets can be held snugly against the wall merely by raising or lowering the rail to suit. Bar steel 3-4 inches diameter is the material used for the rail and the eye bolts are large enough to provide for a loose fit.

Recent research into the use of sodium silicate (water glass) as a detergent indicates that it can be used to aid the action of, or even to replace, soap.

The plating of metal articles with chromium to make them stainless has been accomplished by Sheffield metallurgists. It is expected this process will extend still further the use of stainless metal.

#### WAGE DEFLATION IN SOUTH AFRICA

Wages paid to white workers in South Africa at present show a considerable decline from the levels reached in recent years. When a comparison is made between wages on December 31, 1920, and October 1, 1922, it is found that the gold and coal mining industries have made drastic reductions; in fact, in some classifications wages are even below 1915 levels. In the gold-mining industry wages show an average increase of 10 %, as compared with 1914; this increase is considerably below the Government figure for the increased cost of living. Wages of coal miners in the Transvaal have increased 14.6 per cent over 1914, and in Natal, 26.6 per cent. It is apparent from such figures that the purchasing power of the mining communities has been curtailed considerably.

Wages in other industries, although below the 1920 level, show the following increases, as compared with 1914: Engineering trades, 25 per cent; building trades, 30 per cent; governmental transport and communication services, 34 per cent; and the printing trade, 50 per cent. —U. S. Commerce Reports.

At the present rate of production, the silver output of Mexican mines for 1923 will total about 961½ million ounces—a record amount. A large part of the Mexican silver is recovered in conjunction with other metals, and the good markets for the latter has helped the output of silver.

The attention of British investors and manufacturers has been drawn to the excellent chance they have now in Roumania. Germany's former trade ascendancy in that country was in process of renewal after the Armistice; but the discrepancy in the exchanges and the gradual increase in the cost of manufacturing in Germany has made the Roumanian market unprofitable. The French occupation of the Ruhr district has made it still more difficult for Germany to trade in Roumania.

Recent exploration in Ecuador has showed that it will be an important producer of oil. The known petroliferous areas extend along the coast for a distance of 150 miles north of the boundary of Peru.

British Controlled Oilfields, whose head office is in Montreal, have let a contract for 37 miles of steel pipes to connect their oil wells in Venezuela with the coast at Santa Gracia.

An oil concession covering the famous Baku oil fields in Russia has been granted to J. F. Lacey, who represents American investors. Mr. Lacey has stated in an interview in London that he hopes this contract with Soviet Russia will open the door to general trade relations with the world.

Recent discoveries of copper pyrites in Sweden are considered by the Swedish state officers to be adequate for supplying sulphur for the country's pulp mills, as well as to furnish a substantial amount of copper. Evidently it is still economical to use pyrite in Sweden in place of Louisiana sulphur.

A possible new temporary competitor of the South African diamond fields is Russia, where the Soviet government contemplates the confiscation and sale of jewels from the churches.

# The Mining Districts

BY THE JOURNAL'S CORRESPONDENTS

## NORTHERN ONTARIO

**COMET.**—During the month of February Nipissing mined ore of an estimated value of \$179,239 and shipped ore of an estimated value of \$262,058. All silver is taken at 67 cents an ounce. The refinery shipped 60,336 ounces of silver and the cobalt production amounted to 48,163 pounds. The low grade mill treated 6,047 tons and the high grade plant 217 tons. No developments of major importance occurred during the month.

The new shaft of the Colonial property is down over 800 feet, while that of La Rose on the adjoining Violet property is down 400 feet. The Colonial expects to reach the contact within another 100 feet, and a short distance below this point, a cross cut will be started to the vein. The company confidently expects to encounter good ore at this depth.

**ARGONAUT.**—The directors of the Argonaut Gold Mine have called a special meeting of the shareholders to ratify a by-law for the increase in the company's capital from three to four million dollars. The increased stock will not be sold on the open market, but will be used to pay off loans made by the shareholders, in order that when the company starts producing, it may be free of debt; to purchase additional claims adjoining the Argonaut which are in the direction in which the veins of the Argonaut are being worked; and to amalgamate with the Harmonia Mine which the Argonaut holds under lease. The company expects to have its new mill in operation on April 15th and will probably start on a production of about 50 tons a day until the equipment is tuned up.

**KIRKLAND.** A recent report from the Keeley mine states that the remarkable improvement in the property has come about so quickly that the company has been unable to keep pace in the installation of adequate equipment. Changes, however, are now being carried out and early in the summer it is hoped to have the main shaft so enlarged and equipped that it will be possible to hoist 50 per cent. more ore for the mill and also to carry out exploration on several main veins and numerous branch stringers, which up to the present has been impossible. The mill is also being enlarged and a good deal of additional surface construction is being undertaken. The stock is shortly to be listed on the Canadian market, and will probably come out at \$1.75 a share to correspond with the present English price. The company recently paid a dividend of 8 per cent.

**SHORTAGE OF POWER INCREASES.**—The Porcupine gold mines are faced with the third power cut within a month, and are now operating at much less than half their normal output by electric energy. This condition, however, should be eliminated within thirty days, during which time the spring break-up is expected to occur. The new Sturgeon Falls power unit will also be in commission by that time, and it is to be hoped that the development of the district will now be permitted to go ahead without interruption. While production is naturally much lower, the Dome at least has partly overcome this by milling a higher grade of ore. This, of course, is only a temporary condition, but during the

early part of the present month the grade has averaged round \$20 a ton, which is the highest in the history of the company.

The Coniagas has decided to instal a steel head frame, a compressor and a large hoist on the Newray property. It is not known what significance this installation may have, but it is evident that the Company expects to do a considerable amount of underground work.

**KIRKLAND.**—During the month of February the Teck-Hughes treated slightly under 3000 tons of ore and produced \$105,800, or an average of approximately \$35.50 a ton. Sinking operations are being continued to a depth of 1105 feet, which will be the deepest level in the Kirkland district. Drifts from the fourth and fifth levels have been continued into the Orr property, which is now a source of good ore. The Company is making very substantial profits and should soon be in a position to pay off the money which it was necessary to borrow to complete the purchase of the Orr property and also to retire the bonds.

Developments on the lower level of the Wright-Hargreaves indicate one of the best bodies yet found in the Kirkland district. On the 500-foot level a drift has been opened for a length of 700 feet with both faces still in ore and shows an average width of 15 to 17 feet of ore assaying \$11.00 to \$12.00 a ton. This compares with a stopping width in the upper levels of approximately six feet. Work is also being carried on at the 700-foot level where the indications are that a deposit found at 500 feet will be equally important at 700 feet. The shaft is rapidly approaching the 1000-foot level, and as soon as this is completed, drifting will be started at 850 and 1000 feet. Plans are being made for the increase in the mill capacity to 300 tons a day.

The shaft in the Kirkland Lake Proprietary has reached a depth of 690 feet and will be continued to 800 feet. A station is being cut at 675 feet from which development will be undertaken. Alterations are being made to the mill which will permit the treatment of 150 tons a day as soon as the mine development permits.

**GOLD PROPERTIES CHANGE HANDS.**—Several new mining deals in the Kirkland Lake and Porcupine district are reported. In Porcupine, the Scottish Ontario has been taken over by the Canyon Mines Ltd., which is financed by British capital. La Rose has made a contract for 5000 feet of diamond drilling on the Moyer-Bremner property, which it recently acquired under option, and work is to be started immediately. The Whelpdale has been acquired by the Crystal Copper Company of Butte, which is also interested in the Paymaster and adjoining properties. In Kirkland Lake, the Kitchener has been acquired by A. D. Miles of the Anglo-Canadian Exploration Corporation, as has also the Imerson in Larder Lake. Mr. Miles represents the British house, John Taylor & Sons, who are particularly interested in the future of Northern Ontario gold mines, and are very active in acquiring properties.

The gold production of New South Wales, Australia, during 1922 was £107,139, a little more than half that of 1921. Since the discovery of gold there in 1851, £63,000,000 has been won.

## NOVA SCOTIA

**OPEN SHOP FOR SYDNEY STEEL PLANT.**—There was considerable disappointment when President Roy Wolvin visited Sydney some time ago and apparently did or said nothing to help clear up the industrial situation before he left, — except to talk to the Board of Trade. Of course, that in itself was good business, and since then the membership of the Board of Trade has showed a large increase, the new members being very enthusiastic for good trade conditions. Business in Sydney has not responded to the new spirit and there is a feeling that something will happen before long either to clarify the atmosphere or make it worse; so what is known as the waiting attitude has been adopted by most business men of Sydney.

President Wolvin has now, however, declared the policy of the British Empire Steel Corporation, which is as follows:

"The policy of the Dominion Iron & Steel Company, Limited, is to maintain an open shop. We will not discriminate against union men, but will preserve the right to engage any man, union or non-union, who desires to work at the plant.

"The check-off system is wrong in principle, is not in effect at any large steel plants, and will not be accepted by this Company.

"The present orders were taken to increase production and reduce costs and the average prices received, which were competitive, do not cover the cost of manufacture at the present time. However, market conditions indicate that further orders will be obtained at better prices.

"Our first consideration has been to provide employment and we are prepared to consider an increase in wages for our men if we secure orders for the plant that are profitable but until this can be reasonably assured we cannot make a definite announcement."

This policy is in keeping with that followed by all large Steel Corporations in the United States. This does not seem to carry any weight with officers of the Sydney Steel Workers Union, who declare "that they have a right to the check off and an increase of wages". The check-off will never be granted while relations between the workmen and the company are strained to the breaking point through the hostile and aggressive action of the workmen, led on by rash, unbalanced and redblind leaders. The increase hinted at may be put into effect before the storm breaks. Again, the statement made by President Wolvin that the men will share in the profits as these are made goes much farther than the first or even second increase. It states definitely that the interests of the workmen on the Steel Plant are neither to be neglected nor forgotten. There is no doubt that a statement of this kind will go far to mollify the better class of workmen, and if this promise is fulfilled and an increase given, the radical leaders may find it very difficult to bring on a strike at the Sydney plant and carry it to a successful completion.

**STRIKE THREAT INJURES COAL TRADE.**—Mr. A. Dick, General Sales Agent of the Dominion Coal Co., states that the outlook for the coal trade is very good. "By dint of hard and unceasing work, we have won back the St. Lawrence market, and now having it, the problem is to keep it. Our coal is superior to many grades of American coal, both for industrial and for domestic purposes, and in the circumstances our manufacturers and householders will give the Canadian article the preference. But they fear industrial strife, and say with some reason, 'What is the use of engaging with

the Dominion Coal Company to supply us with so much coal per month, when perhaps in the middle of the season, the men may down tools, thereby cutting off our supply?'" This is an argument which appears easy to meet in Cape Breton, but in Montreal and Toronto not quite so easy. All talk of stabilizing the coal trade of Nova Scotia must remain in the background until such time as the strike spectre has been forever laid. Whether or not the Dominion Coal Company can retain the St. Lawrence trade, depends to a large extent on the conduct of the miners of this Province. If the men show a desire to stick to their jobs, then all will be well, but at the least sign of friction between the operators and the United Mine Workers, buyers will shift their purchases to the American side."

Unfortunately there is all too much truth in Mr. Dick's statement, and the good faith necessary to carry through wage agreement has been at times sadly wanting. True, the President of the United Mine Workers openly expressed strong hope for prosperity during the period of the present contract; yet when the recent strike was on statements were made at public meetings that cast doubt on the sincerity of the officers of the United Mine Workers. Whatever these statements may have meant to the outsider purchaser of coal, who, as Mr. Dick says, is easily scared, they meant little to those who know the workmen of the colliery districts. Should a strike occur at Sydney the miners will not lay down their tools and quit. They are quite content at present, and in spite of all that is said about them, they do hold a wage agreement as sacred, or at least enough of them do to split the U. M. W. organization should any attempt be made by their leaders to cause them to violate it.

**INTERNATIONAL BOARD INVESTIGATES.**—After the grilling that the International Board Members have given President Livingstone on the sanctity of wage agreements and the madness of the officers of District 26 in making application to join up with the Red Internationale of Moscow, there is little to be feared from sympathetic strikes. In the language of one of the members of the U. M. W., Mr. Livingstone before the International Board, "was made to look like a monkey. He was turned inside out, and upside down, and showed such feebleness of mind and want of knowledge of the common affairs of industry, that his reputation as a leader is gone". Whatever we may think of labor unions, the members of the International Board of the United Mine Workers have taught the officers of the Nova Scotia District that loyalty to one's country can be best expressed by being loyal to the institutions and industries of the country, and that trade stability and industrial progress should be fostered by all whose interests are directly bound up with them. Another good feature of the international probe as to where District No. 26 is heading, is the publication of the facts in one at least of the local papers in the Glace Bay district. There is nothing like letting the light in, and it is beating with a fierce heat just now, and somehow Moscow does not seem to be quite as attractive as before.

**THE OLD AGE PENSIONS.**—A grand farce was staged before the Halifax legislature last week, with Secretary McLachlan as the leading actor. Some time ago a number of delegates (miners) from Cumberland, Pictou, and Cape Breton Counties, met at Antigonish to consider the matter of old age pensions for miners. Being moderate they agreed that a miner over sixty years of age was entitled to forty dollars per month, and decided to interview the Government at Halifax and present their case. Silby Barrett, International Board Member, was

The head of the delegation, but when he and his friends arrived they found that they had been forestalled by J. B. McLachlan and others. These men had gone one better and instead of asking for the paltry sum of forty dollars per month for the few Nova Scotia miners over sixty years of age, they asked seventy dollars per month for every workmen in Nova Scotia over that age. It was pointed out that it would take twenty million dollars to do this, and when Jimmy was asked where all this money was to come from, he replied, "the industrial income tax". Needless to say, the curtain was rung down and will not be lifted again until this little Province with its four millions of revenue has ~~one~~ <sup>over</sup> its freight. But an International Officer was sidestepped, which was very pleasing to the irrepressible Jimmy. All is not going well between the Reds and the Moderates. The spirit of Robert Baxter is ranging over the District, and nemesis is following fast.

### BRITISH COLUMBIA

**CEDAR CREEK, CARIBOO.**—Gold to the value of about \$145,000 has been recovered from the placer ground of the Cedar Creek Mining Co. up to a few weeks ago, according to F. S. Munson, the general manager. One sluice box is being operated and a second soon will be in use, when production will be doubled. The company is paying for its claims from the yield and expects to have this liability cleared off by April next following which a substantial sum will be invested in development.

It is not long since rockers were displaced by the sluice box on Cedar Creek. Water for the latter consists only of that which drains into the shaft and is forced through a four-inch pipe into the box by a turbine pump. Another of these pumps is being shipped over the snow for use in connection with the second sluice box.

There has been a considerable amount of drifting done and a government official who inspected the field a short time ago says: "I saw a wonderful pay-streak about two feet above bedrock from which nuggets could be picked out with the fingers. One of the miners struck a 'pocket', one shovelful from which contained 13 ounces 5 dwts of gold."

The sluice box in use is about 2 by 68 feet with a run-way of 8-inch riffles. Clean-ups are made about every three days. The greatest return from a single clean-up was 467 ounces and the lowest 36 ounces.

The Cedar Creek diggings are about six miles from Quesnel Dam, Cariboo, and from the present conditions it seems to be assured that there will be a permanent camp at the Dam for at least the next two or three years. This summer it will have about 200 residents with between 500 and 600 men working in the vicinity. The Cedar Creek Mining Co., is erecting a large sawmill near its property.

**PORTLAND CANAL'S RECORD.**—There was a production of over ten million dollars in the northwest districts of British Columbia in the year 1922, representing an increase of more than fifty per cent. over the previous year. So many properties have been brought practically to the production point that the coming season should see exceptional progress.

George Clothier, government mining engineer, bubbles with enthusiasm when discussing prospects in the Salmon, Bear and Nass river sections of the north. Just down from the snow-bound north, he has been

busy telling of the mineral wonder of the Portland Canal, Alice Arm and other regions with which he is officially concerned.

What better record, he asks, could be looked for than that of the Premier Mine with its production in less than two years of \$8,000,000 in gold and silver, its dividends of \$3,150,000 or 63 per cent on its capitalization, and its shipment in 1922 of 70,000 tons of ore containing 120,000 ounces of gold and 4,000,000 ounces of silver? This is a greater production of silver than that of the whole province for any one previous year. Output is regulated by the capacity of the mine's eleven miles aerial tramway, now capable of handling from 200 to 250 tons a day, which may be increased to 300 tons a day. Hitherto ore has been taken from above No. 4 level and diamond drilling has shown that there is good ore below this level. Besides carrying on active development of its first holdings, the company has been acquiring adjacent properties.

More light is thrown by Mr. Clothier on the policy of the Granby Consolidated Mining and Smelting Co. which recently has given evidence of extending its operations by adding to the Anyox smelting plant greater and more reliable power resources, a new concentrator, the acquirement of northern prospects and their development, to say nothing of the taking over of the Copper Mountain Mines and plant. Regarding these embryo mines, viz., the Outsider group, Maple Bay; the Sunshine group, Glacier Creek; and the George group, Bear River; it is stated that the former will be shipping to Anyox early this year and that both the latter are giving promise of becoming important copper ore producers. If the George group proves up to expectations it will mean the extension of the Bear River railway, and the consequent opening of the Nass River mineralized zone. Mr. Clothier says that the department of mines has built about twenty-five miles of miners' trails on the Nass side of the mountains and he considers the possibility of railway connection a matter of importance from a mining viewpoint. It is clear at any rate that the Granby Company proposes that its future supply of smelter feed shall be assured.

Other properties mentioned by Mr. Clothier are the B. C. Silver Mines Ltd., near the Premier, in regard to which he confirms reports of the encouraging showings recently uncovered; the Indian Mines Ltd., which has proved a large body of milling ore; and the Big Missouri, abandoned by Sir Donald Mann as a result of adverse reports, subsequently bonded by Messrs. Trites and Wood, of Fernie, large holders in the Premier, and which on late development seems to be disproving pessimistic statements as to its value, the sinking of a shaft having shown high-grade ore at a considerable depth.

It is admitted that the Dolly Varden mine's unfortunate decline has been a set-back to Alice Arm; but Mr. Clothier does not think the last has been heard of this district. He expects to see the Engineer mine, Atlin, become one of the large lode gold producers of the Province. For years litigation has had this property in its grip. These difficulties now have been cleared away and action should follow.

He said, too, that there were important placer mining developments on McAdam, Dease and Thibert Creeks and that the possibilities of the Dease Lake country, in this respect, would stand full investigation.

**PORTLAND CANAL PROSPECTS.**—No further evidence of mining activity in the Portland Canal Mining Divi-

sion is necessary than the number and variety of properties reported to be changing hands, to be under development, or to be about to receive attention. Here are some of them.

Gustave Seiffert, with a bond on the Rufus group of seven claims 18 miles from Stewart on the north side of Bear river, is said to have returned north with enough financial support to carry on development. Several outcrops of high-grade ore are reported to have been located, samples from which run as high as 444 oz. in silver. The prospect is at an elevation of 2400 feet and two and a half miles of trail will have to be constructed to make it accessible.

The Gloria group of twelve claims, Bulldog creek, between Marmot and Georgia creeks, will be explored by a company organized in Seattle. The terms provide that the company is to spend \$70,000 on development, less 20 per cent. for promotion. A. Lineke, of Hyder, the owner, will be manager of the work.

The B. C. Silver Mines Ltd. have opened their own assay office at the mine with J. C. Comrie, who was similarly employed at the Dolly Varden mine, in charge.

Development is proceeding on the Prince John group and is expected to have advanced sufficient in a few months to warrant installation of more plant. This property is in the Bear river district.

A considerable quantity of good milling ore is reported to have been opened up on the Titan group, Fish creek.

**INCREASED TAXATION OF CLAIMS?—**Whether the provincial government would be justified, through increased taxation, in compelling continuous development of crown granted mineral claims is a question upon which there is decided difference of opinion. Some weeks ago an organization at Silvertown, a mining town of the Slocan, passed a resolution deploring the number of unworked claims held idle by their owners. The contention was that the tax of 25 cents an acre on crown granted mineral claims was much too low, that it had the effect of countenancing the holding of such claims speculatively, and that men desirous of doing actual development were being discouraged by the condition. The Vancouver Island Prospectors' Association, however, declares that crown granted mineral lands are taxed as heavily as is warranted, that an increase would mean the reversion to the Crown of many which now are revenue-producing, and points out that already 2,500 such claims have come back to the Government, winding up by asserting that no effort should be made to insist on continuous development of mineral lands until the Administration is prepared to "compel the continuous operation of coal, pulp, timber and agricultural areas held under Crown grants."

**PREMIER ACQUIRES MORE CLAIMS.—**The Mineral Basin group of claims, near the Premier Mine, Salmon River, is reported to have been acquired by interests associated with the Premier Gold Mining Co. This group adjoins the Northern Light claims, which are controlled by the B. C. Silver Mines, Ltd. Its surface showings are not particularly attractive but the property lies on the main strike of the known ore-bodies and for this reason, no doubt, has been taken over for the Premier.

**ALICE ARM.—**The Homestake Mining Co., whose holdings are on the headwaters of the Kitsault River, Alice Arm district, plans resumption of development this summer. The last work done here was in the summer of 1921 when it was reported that a body of

ore had been broken into containing good values in gold, silver, and copper.

**ORE FROM KENO HILL.—**Reports from Dawson Y. T. are to the effect that, as a result of the winter's work at Mayo, there will be 8,000 tons of ore at Mayo Landing for shipment when navigation opens. The caterpillar truck is said to have proved a pronounced success. Weather conditions, however, severe, have not interfered with their efficiency.

**B. C. ORE EXHIBITS FOR LONDON.—**Inquiries received from England at the B. C. Department of Mines indicate that keen interest is being manifested at present in the mining industry of British Columbia. Information is sought particularly of developments in the Portland Canal district, although the attention of prospective Old Country investors is not confined to that region.

As a result of this situation the Hon. Wm. Sloan, Minister of Mines, has had a collection of the ores of the Salmon River area prepared and shipped for display at the offices of the Agent General for British Columbia, London. Included in the exhibit are some fine specimens of the rich gold-silver bearing ores of the Premier Mine. Mr. F. C. Wade, the Agent General, will give the collection a prominent place in British Columbia House.

The Department, Mr. Sloan states, also is assembling a representative exhibit of the ores of the different mineral producing districts of the Province for the great Empire Exposition to be held in England next year. To get together samples from all sections that will adequately illustrate the mineral resources of the Province is not a task easily accomplished. The work has been in progress for some months and when the display is complete it probably will be the finest of its kind that has ever left British Columbia. Exceptional care is being exercised in the preparation of this collection because of the importance of the Empire Exposition as a medium of international publicity.

**INCREASED COMPENSATION TAX IN ALBERTA.—**The coal mine operators of the Province of Alberta are protesting against a proposed increase of compensation rate under the Alberta Workmen's Compensation Act of from 55 to 66  $\frac{2}{3}$  per cent. but there is no indication that Premier Greenfield's government is prepared to make any concessions.

Representatives of the collieries admit that the change would put Alberta's rate on the same plane at that of other provinces but they claim that comparisons are not fair because of the high wages paid in Alberta. True 66  $\frac{2}{3}$  is the basis in Ontario, but there metalliferous miners receive \$4.50 a day while in Alberta mines the wages are \$7.50 a day and upwards. An independent body of men in the first instance, it was stated, had fixed upon \$10 a week as sufficient for compensation, but there had since been a steady advance as a result of pressure by labor organizations on the government.

Premier Greenfield has retorted that such an assertion is not correct, that if labor's demands had been acceded to, increases under the Workmen's Compensation Act would have amounted to thousands of dollars annually, and that the increases proposed would not total more than \$10,000 from the mining industry, or one-sixth of a cent per ton on the coal mined in the province.

This, it was said, had no bearing on the principle involved and that while miners wages were maintained

on a war-time basis there was no reason for increasing compensation.

**FEBRUARY COAL OUTPUT.**—The coal output of British Columbia for the month of February totalled 244,042 tons, comprising 128,389 tons from Vancouver Island collieries, 26,449 from the Nicola-Princeton district and 89,204 from the Crow's Nest Pass.

**MR. WARREN'S ADDRESS.**—J. J. Warren, president of the Consolidated Mining and Smelting Co. of Canada, gave an interesting address recently to the Associated Board of Trade of Eastern B. C. on the mining situation, one of the most important statements made being that Rossland, one of the historic camps of the Province which for some years has been practically dormant, may be expected to become active in a short time.

As to the mining industry, he stated, "We have had prices that are too high. The reason I say this is that these high prices result in the working of some properties that should not be worked, and that can only be worked while prices are high. We would be far better off with lower prices and more stable conditions. The main trouble with high prices is that there is always a reaction."

"No doubt there is a boom on in the United States. There seems to be there the same feverish condition as existed during the war. For instance, I sometimes take the auto industry as a barometer, and on the other side they cannot supply the demand for autos. Of course there is a resultant call for metals. Yet autos do not make a country prosperous; in fact they take a large number of men away from other and more useful production. And there is a limit to the number of autos a country can afford. We must not be carried away by such feverish conditions."

"Four or five months is about as far ahead as we can look in the metal line just now. We seem to be all right; I hope that we shall be all right, for Trail would really be about the last place that would be shut down."

Discussing the standing of the company, Mr. Warren stated that at the present time more power was a necessity and in that connection he stated "we are lucky to have Mr. Campbell (Lorne A.) who has done so well in power development, and it won't be my fault if he doesn't develop some more."

Conditions, stated Mr. Warren, were not bad; in fact they were fairly good. That was as it should be, and he disliked to see people getting excited because things were going well. Referring to the U. S. tariff, he declared that one would rather think that there ought to be a limit to which a tariff could rise. If a country was to be developed local conditions rather than foreign conditions should largely control prices. Only 50 per cent. of the metal produced at the Trail smelter was consumed in Canada. In fact the company had sent some to Germany and had been paid for it, and had not taken German marks either!

"Our policy is to increase domestic consumption," declared the speaker. "We make special prices to Canadian manufacturers to enable them to export their manufactures. Consequently many of these are increasing production, and this means more prosperity for Canada. When we have to send over 50 per cent. of our products to the ends of the earth and compete there with all comers you will understand that we do not receive the prices generally quoted in the press. We are not at all alarmed about the future, but I expect we are bound to have some reaction within the next six months."

Mr. Warren announced that he had recently visited

the Sullivan mine with the general manager, S. G. Blaylock, and could say that the new mill there would be running shortly.

"We expended \$300,000 in 1922 to carry on in Rossland," asserted Mr. Warren, "and in view of that I do not think that we deserve any criticism. Our policy was to keep going until the Sullivan mill was ready, but when we found that the price of coke was not to be reduced, it would have been folly to continue. We feel, however, that much is in store for Rossland and that by this time next year it will be going strong."

S. G. Blaylock, general manager of the company, also addressed the convention, remarking that when the delegates visited the plant and saw the copper plant standing idle they would be glad that they had passed resolutions aimed to aid the copper industry.

#### PURCHASE OF GOLD ORES

The attention of prospectors and others is drawn to the provision in the Mining Act of Ontario authorizing the Department of Mines to purchase parcels of gold ore taken out by prospectors and others in developing or working mining claims. Arrangements have been made by which such parcels of gold ore, whether large or small, will be accepted by the Timiskaming Testing Laboratories at Cobalt, and paid for according to the schedule provided for the purpose. The Laboratories are operated under the auspices of the Department of Mines.

This offers a first class opportunity for testing the value of ores on a large scale, and also of turning ore of good quality into money for carrying on further development work. By special arrangements, on less than carload lots, freight rates on the T. & N. O. Railway are reduced 50 per cent.

The Laboratories are also equipped for working out the best methods of treatment for gold or silver ores of a refractory or unusual character.

Full information as to treatment charges, schedule of payments, etc., can be obtained from the undersigned, or from A. A. Cole, Manager, Timiskaming Testing Laboratories, Cobalt, Ontario.

**THOS. W. GIBSON,**  
Deputy Minister of Mines.

Toronto, 12th March, 1923.

#### FOR SALE

Complete equipment of a first class Assay Office in Sudbury, Ontario. Consisting of: Crushing equipment (Braun, Balances, furnaces, etc.). This equipment is almost new as the office has only been in operation one year. Any reasonable offer will be accepted. Apply T. Brodie Brown & Co., Nickel Range Hotel Block, Sudbury, Ontario.

up to within a few days of publication.

THE  
**MINING MANUAL**  
AND  
**MINING YEAR BOOK**  
**1923**

By **WALTER R. SKINNER.**

The Standard Reference Work on Mines

Price **20/- net.**

Post free(Inland), 21/-. Post free(Abroad), 21/6

1,000 pages. In Demy Svo. bound in **RED** Cloth.

**A Recognised Indispensable Work of Reference**  
For **MINING INVESTORS, MINING ENGINEERS,**  
**MINE MANAGERS, BANKERS, STOCKHOLDERS,**  
**DIRECTORS** or anyone interested in the **MINING**  
**INDUSTRY**

**COMPLETE AND UP-TO-DATE PARTICULARS** concerning 1,350 Mining Companies operating in all parts of the world. Gold, Diamond, Silver, Copper, Tin, Iron and other Mines, Collieries, Exploration, and Mining Investment Companies, arranged in alphabetical order.

**PARTICULARS** given of each Company include the Directors and other officials; date of establishment; seat of operations; description of the property, with the purchase consideration; plant erected or in course of erection; present working results; ore reserves; details of capital; calls; dividends paid; and the financial position as disclosed by the latest accounts. Highest and lowest prices of the shares for the last three years, also latest price.

**Directors** (3,700) and Mining and Consulting **Engineers** and **Mine Managers** (900), their addresses and names of the Companies with which they are connected.

**SUPPLEMENTARY INDEX** of private, dormant or Companies which have ceased to be of public or market interest. One of the most useful and important features of the book. It is the only list of its kind published.

**CRUSHING TABLES** and Outputs from the principal Gold mines are given at the commencement of the volume, showing tons treated monthly, results obtained, and yield per ton; also annual yields.

**DICTIONARY OF MINING TERMS.** — An up-to-date glossary covering 437 mining terms by the use of which mining developments can easily be followed. The difficulty of understanding technical phraseology is thus easily mastered.

To be obtained from all Booksellers,  
or direct from the Publishers,

# PROVINCE OF QUEBEC

## MINES BRANCH

Department of Colonization, Mines and Fisheries

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, etc.

MINISTER OF COLONIZATION, MINES AND FISHERIES, QUEBEC

**MINER'S CERTIFICATES.** First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is \$10 and is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

**WORKING CONDITIONS.** During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

**SIX MONTHS AFTER STAKING.** At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

**MINING LICENSE.** The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year, and a fee of \$10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days' labour on each forty acres.

**MINING CONCESSION.** Notwithstanding the above, a mining concession may be acquired at any time at the rate of \$5 an acre for SUPERIOR METALS, and \$3 an acre for INFERIOR MINERALS.

The attention of prospectors is especially called to the territory in the North-Western part of the Province of Quebec north of the height of land, where important mineralized belts are known to exist.

**PROVINCIAL LABORATORY.** Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, Montreal, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

**HONORABLE J. E. PERRAULT,**

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

# BRITISH COLUMBIA

## The Mineral Province of Western Canada

Has produced Minerals valued as follows: Placer Gold, \$76,177,403; Lode Gold, \$105,557,977; Silver, \$55,259,485; Lead, \$18,330,575; Copper, \$166,393,488; Zinc, \$21,848,531; Coal and Coke, \$225,409,505; Building Stone, Brick Cement, etc., \$31,072,016; Miscellaneous Minerals, \$1,210,639; Making its mineral production to the end of 1920 show an

**Aggregate Value of \$734,259,619**

The substantial progress of the Mining Industry of this Province is strikingly exhibited in the following figures, which show the value of production for successive five-year periods: For all years to 1895, inclusive \$94,547,241; for five years, 1896-1900, \$57,605,967; for five years, 1901-1905, \$96,509,968; for five years, 1906-1910, \$125,534,474; for five years, 1911-1915, \$142,072,603; for the year 1916, \$42,290,462; for the year 1917, \$37,010,392; for the year 1918, \$41,782,474; for the year 1919, \$33,290,313; 1920, \$35,543,084; 1921, \$28,066,641.

**Production During last ten years, \$336,562,897**

Lode-mining has only been in progress for about twenty-five years, and not 20 per cent. of the Province has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those of any other Province in the Dominion, or any Colony in the British Empire.

Mineral locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with Mining Reports and Maps, may be obtained gratis by addressing.

VICTORIA, British Columbia.  
THE HON. THE MINISTER OF MINES

# Ontario's

# Minerals

PROVINCE OF ONTARIO

DEPARTMENT OF MINES

HON H. MILLS, Minister of Mines

## Mineral Areas.

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favorable for the occurrence of minerals, 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver mines of Cobalt occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

## Economic Minerals.

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario:—actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluor-spar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, portland cement, brick and tile, meet every demand.

## Mineral Production.

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1921 to be worth \$48,128,387, of which the metallic production was \$27,574,202.

The following figures show the rapid growth of Ontario's mineral industry by five-year periods since 1891:

| Year.        | Value.      | Year.        | Value.       |
|--------------|-------------|--------------|--------------|
| 1891 .. .. . | \$4,705,672 | 1906 .. .. . | \$22,388,383 |
| 1896 .. .. . | 5,235,003   | 1911 .. .. . | 41,976,797   |
| 1901 .. .. . | 11,831,086  | 1916 .. .. . | 65,303,822   |

## Dividends.

Dividends and bonuses paid to the end of 1921 amounted to \$23,140,734 for gold mining companies, and \$84,388,185 for silver mining companies or a total of \$107,528,919.

## Mining Regulations.

A miner's license costs \$5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of \$2.50 or \$3.00 per acre, depending on location in unsurveyed or surveyed territory.

## Assay Office.

The Provincial Assay Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

## Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

## PREMIER MINE REPORT

We are pleased to have for publication today, through the courtesy of Mr. H. A. Guess, his first formal annual report of the operations of the Premier Mine, of which he is vice-president and managing director. We are especially happy to include this report in our pages because it presents such a pleasant contrast to the financial management of some other mines upon which it is our duty to comment from time to time. Not only does the report deal with a phenomenally successful mining venture, but it also constitutes a model of straightforward mine management and accounting, concealing no essential detail, conveying no false impressions, and stating unfavourable as well as favourable aspects of present and future operations with an impartiality that marks the high value placed upon their own professional reputations by the men concerned in the direction of the mine's destinies. Of the seven directors, Mr. W. R. Wilson and Mr. R. W. Wood, both of Fernie, B.C., as well as Mr. Guess, are Canadians. All are decided assets to Canada's mining industry.

With broken ore in the stopes to a value of 2½ million dollars and ore blocked out but not broken estimated at 9½ million dollars, the immediate future of the mine is assured. The unexplored portions both of the veins being worked and of the ore-bearing zone within the limits of the company's property offer additional possibilities for profitable mining. But Mr. Guess says plainly that the extraordinarily high-grade ore that has made the mine famous does not occur below the third level, nor is it likely to be found at a greater depth beneath the surface. It is not known to what depth the milling ore will extend.

It appears now that in this newest camp of the Portland Canal district, as in most other mining districts, the larger part of the production will be won from ore of moderate or low grade. Hence Mr. Guess' warning that the high-grade ore is due to surface enrichment and persists only to comparatively shallow depths need not be considered discouraging. The plans of the Premier company evidently contemplate the use of their ore of lower grades long after the bonanza shoots are worked out. Several other properties in the vicinity already show ore of moderate grade in at least moderate amount, and we can hope logically that ore of average grade, even if not of the bonanza variety, will feed a number of flourishing concentrating mills within the near future.

## THE PIERIAN SPRING

That respectable and elderly daily newspaper, the "British Whig," Kingston, Ont., recently turned its editorial attention to the discovery of gold in Rouyn township, Quebec. Gravely, sadly, and reprovingly the estimable "Whig" moralized on the wickedness of the "mad rush" of prospectors and adventurers "to that barren piece of land in the wastes of Quebec." A lofty note was struck in these monitory sentences: — "All are going with the same high hope of making a rich strike. Many of them are forsaking their homes, and are staking everything they own on the chance that they will be amongst the favoured ones to strike a *yellow pocket* and return with *fabulous riches*. They are prepared for *hardship and suffering* in order that they may not lose the opportunity of a gamble with the precious metal which stands for so much in the world to-day." (The italics are our own.)

More moralizing follows. It is pointed out in one ever-to-be-remembered sentence that "there is something of the prehistoric in the way in which men grovel in the soil." California and the Yukon are alluded to. "Shattered hopes" and "wearied frames," according to the "Whig," will be the inevitable guerdon of the ill-advised seekers after "yellow pockets." We too are sure that this will be the case if the "adventurers" are stupid enough to "grovel in the soil."

Alas, we fear that the "Whig" is living in the melodramatic past. Its ideas of prospects and prospecting belong to another age. They are antedated by about three-quarters of a century. Gold miners do not nowadays expect or look for fabulous riches from "yellow pockets" in Quebec or elsewhere. Nor are hopes based upon striking the "vein which is supposed to run through the district." Nor do men get rich by selling "false veins" — whatever that may mean. Nor are there any dangers on the trail or in the camp. Nor yet are there any considerable hardships. The sad fact is that the "Whig" has been writing nonsense about a subject of which it is painfully and patently ignorant.

The "Whig" should know that the mining engineer, the geologist, and the trained prospector have made gold mining safe for democracy. We regret that it is our duty to tone down the lurid colours of the "Whig's" picture. The prospector is a well-fed, well-paid individual, who is by no means given to "staking his all" on one field. The natural desire to get in ahead of the other man the "Whig" will find exem-

plified in every walk of life, — at the ticket offices of theatres, in retail establishments, and, particularly, in politics. We venture to say that in any one of our periodical political campaigns there is more money wasted, misapplied, and misappropriated than in a dozen "wild rushes" to new gold territory. And from the gold rushes the country *does* get some benefit.

The well-provisioned prospecting party of to-day needs no commiseration and deserves no reproach. The useless, or mischievous, hanger-on is rapidly passing out of existence; what evidence there is of his activities is provided in great part by noxious stock advertisements published in our daily newspapers.

Perhaps the "Whig" will find food for thought in this.

### BRITISH EMPIRE STEEL REPORT

The affairs of Canada's greatest single mining and metallurgical company were treated with frankness and decision last week at the annual meeting of the British Empire Steel Corporation. President R. M. Wolvin's proposal to reduce the capitalization by half, to \$250,000,000 was approved heartily by the shareholders. Labor conditions in and about Sydney were discussed at some length and measures proposed with a view to closing the present breach between the company and its workmen. The report of an unsatisfactory business year during 1922 was followed by a forecast of better results during the present year.

From the beginning it has been commonly realized that the \$500,000,000 capitalization is badly out of proportion to the earning capacity, either present or prospective, of the corporation's constituent companies. The corporation holds tremendous and invaluable assets in its coal seams in Cape Breton and its unique beds of ore in Newfoundland. An attempt was made to justify the capitalization on the basis of these assets — an attempt without justification, as the time factor was ignored. The assets contained in these deposits of coal and iron ore can be realized at an annual rate that is almost infinitesimal in comparison with their extent. Hence a soundly based balance sheet must discount the present value of these assets to a degree that is hardly believable until demonstrated mathematically.

This reduction of the capital stock not only tends to satisfy the demands of sound accounting, but also is calculated to affect materially the attitude of the corporation's workmen. These men have believed, and rightly, that the profits reaped by the corporation from their daily toil were to be applied as dividends on "watered" stock. Insofar as "watered" stock was issued and paying dividends, either before or since the organization of the present corporation, the workmen were being imposed upon and a morally illicit tax put

upon their industry. Now, happily, a large part of the recently added cause for fear has been removed, though the financial dilution of the stock of some of the original companies of necessity remains.

The promise of a rise in wages to the steel workers should conditions permit is a palliative of more temporary nature, though its effect should be distinctly salutary. It is a natural and inevitable sequel of the rising wages in the steel mills of the United States. The suggestion of still further rises in wages, should the steel company's earnings warrant it, is of more far-reaching importance, and should the directors mean it and the workmen accept it, as a promise, there is no doubt that the labour problem at the mills will be well on the way to solution.

Those conversant with both sides of the labour tangle at Sydney realize well the fact that most of the demands made on behalf of the labour unions there have been instigated by and formulated by professional leaders of revolutionary tendency. This has been abundantly evident during the last year or more. Sydney and the surrounding industrial communities have become the happy hunting ground of professional agitators, who up to the present have remained immune from the process of law to which their actions make them morally, even if not legally liable. The directors have with justice refused to consider the demands of unions at present under the control of these leaders. Some of the demands doubtless have reason on their side; but all must be refused until such time as the local unions are directed by safe and sane leaders, more nearly representative of the true character of Canadian workmen.

The review of the physical condition of the corporation's coal mines is particularly satisfactory. A substantial capital investment has been made for the double purpose of ensuring a long and secure life for these under-sea collieries and of providing for the more economical working of the seams. When the plans now inaugurated have been completed, the collieries of Nova Scotia will rank with the best in any land in point of effective engineering management.

One of Mr. Wolvin's announcements that holds great possibilities for the future both of his corporation and of Canada is that dealing with the manufacture of coke for household use. There is no reason to doubt that the recent proposal of the Dominion Fuel Board is commercially feasible, and the obvious point of attack in substituting this native fuel for imported anthracite would be Montreal. Recent advances in coke-oven practice have reduced the cost materially, so that the manufacture of coke for domestic use is now an even more attractive proposal than it was when the existing successful plants for that purpose were established. We hope the British Empire Steel Corporation may find it feasible to erect a coking

plant in Montreal as a means both of expanding its own earning capacity and of extending its usefulness to Canada.

### TEMISKAMING TESTING LABORATORIES

Some months ago we drew attention in these columns to the fact that the Temiskaming Testing Laboratories at Cobalt, operated under the direction of the Department of Mines, Toronto, is prepared to extract the gold from small lots of ore, to return to the owner the value of the bullion less treatment charges, and to give a full report on the method of treatment indicated as advisable by the tests. It is now announced in addition that shipments of larger size will be acceptable to the Laboratories, and that special freight rates on any trial shipments of ore to Cobalt have been arranged with the T. & N. O. Railway.

This facility offered to prospectors and others developing their claims promises to be of distinct value to our growing mining industry. Twenty-five years ago the stamp-mill at the School of Mining, Kingston, was used extensively for the same purpose and was highly appreciated by the pioneers in the gold fields of that time. In Australia a variant of the same idea in the form of portable stamp-mills has proved eminently useful to their gold industry, at a comparatively slight public expense.

The testing of the gold ore of prospects from the various camps at the government laboratories in Cobalt should prove to be a valuable adjunct to the work of the provincial geologists. The directing of an embryo mining camp's destinies rests to a considerable extent on the judgment and the field researches of these public servants. Should the results of mill runs from promising prospects be made available to them in addition, their conclusions will be made the more valuable. In this case, as always, the staff of the Ontario Department of Mines can be relied upon for absolute discretion in their use of private information.

In another line of endeavour, that of assaying gold samples, the Temiskaming Testing Laboratories appear, in their zeal in the public service, to have infringed upon private rights. It is eminently desirable that the officials of the Department of Mines should have early and accurate knowledge of developments in the gold fields, that they may perform their public services the better. With this end in view the Laboratories at Cobalt have offered very attractive rates for assaying to prospectors and others. This would be "all to the good" were it not for the existence of independent custom assayers, one of the most valuable human adjuncts to a gold mining camp. It is said that the public laboratory has cut prices to a point that the private laboratory cannot possibly meet. If on investigation it should be found that the publicly subsidised Temiskaming Testing Laboratories now compete thus

unfairly with the custom assayer, the rates should be adjusted to provide for strict justice to the private citizen.

The editorial on Argonaut financing that appeared in these pages two weeks ago, has drawn a vigorous rejoinder from Mr. John E. Hardman, formerly consulting engineer for the company, in the form of the letter we print today. This letter was published in the Montreal "Star" last week, the day after we received it, with the acknowledgement that it was addressed to the "Journal". Our columns are, of course, open to present both sides of a question. Mr. J. H. Rainville, president of Argonaut Gold, Ltd., will avail himself of this privilege next week to give some facts about his company. Though Mr. Hardman's letter is couched in terms that call for a reply, we shall wait until next week to expound further our views on the subject. We await Mr. Rainville's letter with interest.

Tangible evidence of the growing interest taken by substantial London mining investors in Canadian mines is afforded by the press despatch announcing the sale of the Daly-Alaska property to a group represented by Mr. S. S. Denny. This property is, by the accident of the international boundary, in the United States; but it forms one of the group of promising near-mines surrounding the Premier. The camp promises to be an international one, with twin ports at Hyder, Alaska, and Stewart, B.C. Fortunately for Canada, the major part of the mineralized zone as disclosed thus far is east of the boundary.

### THE DIVINING-ROD MAN

He was a man of dignity. His mien  
Was mystical, detached, as if he'd seen  
The Apocalyptic mysteries revealed,  
Or glimpsed the awful Judgment Book unsealed,  
Or was familiar with the spirit world.  
His whiskers were elaborately curled.  
His nose was slightly carmined at the end;  
Not less than seven drinks made him unbend.  
His coat was of ecclesiastic cut;  
He might have passed as missionary, but  
The hat he wore, a Stetson, wide and black,  
Seemed worldly, raffish, strangely out of whack.  
His rod consisted of two whalebone strips,  
Bound tight together at the outer tips.  
With this device he could discover veins,  
Thus obviating all prospecting pains.  
When, half deceiving and half self-deceived,  
He passed away, I doubt if any grieved.  
His day has passed, his type lives on forever:  
Though I don't think the present kind so clever.

J. C. M.

# PREMIER MINE

FIRST PUBLIC ANNUAL REPORT TO STOCKHOLDERS

The following report of Mr. H. A. Guess, vice-president and managing director of the Premier Gold Mining Company, is reprinted from the annual report sent this year to stockholders and made available to the public for the first time. It is dated March 5th.

Although your Company has been in existence for some four years, annual reports heretofore have been merely an informal sort for the reason that there were only 12 or 14 stockholders and these stockholders were all of them in close touch with the current operations of the mine. However, during the past year a small amount of stock (some 2%) has been purchased by various parties not heretofore interested in the Company, and it has therefore seemed advisable to make a formal and detailed statement covering the operations of the year 1922.

The Premier property, comprising 19 mineral claims and fractions, is located in British Columbia, adjoining and just to the northeast of the International Boundary Line between Alaska and British Columbia, and is about 11½ miles almost due north from the town of Hyder, Alaska, which with the adjoining town of Stewart, B.C., on the Canadian side of the line, is located at the head of the Portland Canal. In the body of this report will be found a map showing the Premier Group of mining claims which shows also the location of the development and mining work so far done upon the property. Also another map is embodied in this report showing in plan and section, the workings upon the Premier property as at December 31, 1922.

In addition the Premier Company owns some mining claims which adjoin its main property to the Eastward and it also owns 542,469 shares out of a total authorized issue of 1,500,000 shares of the B. C. Silver Mines, Ltd., which latter Company owns a number of mining claims both to the north and south of the Premier Group.

The orebodies so far discovered and opened up on the Premier are three, two of which are the more important so far and have a northeasterly trend and a northwesterly dip and occur as replacements in quartz porphyry in proximity to andesitic tuffs, also sometimes within the tuffs. These two more important bodies appear, in the light of the development as at present, to merge together their southwestern ends and to the northeastward lie more or less parallel and from 50' to 100' apart.

A large amount of underground diamond drilling has been done with marked success, as a guide for the development work and there are indications from the diamond drilling so far that one or more additional zones of this same northeastward trend may be opened up within the area now under development; but these from present indications, if found to be definite zones will be more likely to be of milling or medium grade ore than of high grade.

The third body within the area under present development has a strike almost at right angles to the other two, namely, to the northwest and a dip to the

southwest. This third body, while showing irregular shoots of good grade ore, has so far been erratic and buncy in its assays and no particular tonnage has as yet been opened up or figured upon. Surface outcrops and shallow cuts at various points to the northwest on the Premier property, give reason to believe that this vein of northwest strike is quite persistent and some 2,500' to the northwest of the main workings lies the Bunting Tunnel, which was started before its acquisition by the Premier to explore this northwest orebody, and it is contemplated, beginning this year, to drive possibly from the Bunting Tunnel upon this northwest orebody to ascertain what, if any, ore of milling or shipping grade it may contain. Work upon this, if started from the level of the Bunting Tunnel could be utilized to thoroughly explore this northwestern vein and at the same time by the continuation of that exploratory drift some 2,500' to the southeast, it would tap the main Premier orebody upon its dip, at a vertical depth of approximately 500' below the fourth or present bottom level of the Premier workings, and would thus drain and facilitate the opening up of the Premier orebodies to that depth, provided future explorations show the orebodies to carry commercial ore to that depth.

There are other surface showing upon the Premier, as yet unexplored, notably upon the Pictou and Cascade Falls No. 8, which will in due course of time be investigated, doubtless by crosscutting to the south from the present bottom level of the Premier main workings.

The Premier property is equipped with an excellent mining plant, a concentration and cyaniding mill of around 4,000 tons monthly capacity and an aerial tramway whose upper terminal is just below the present bottom level of the Premier mine, and alongside the mill, and whose lower terminal ends in a 1500 ton ore bunker, divided for first class and second class ores, at deep tide water at Stewart, B.C., the tramway being approximately 12 miles long, which is one of the longest, if not the longest, tramways for ore in existence. The tramway has a capacity of around 10,000 tons monthly.

The Premier is equipped with a water power plant, developing around 900 H.P. during the months of May to November, inclusive, and during winter months from December 1st to May 1st, the water power is variable, dropping to as low as 200 H.P. during very cold weather, and the power during these months is supplemented by semi-Deisel engines, the oil being pumped from tank steamer at Stewart to storage tank above the lower terminal of the tramway and thence transported in drums over the tramway and distributed by tank and pipes from the upper terminal to engines.

A summary of mining operations for 1922 is as follows:

|                                                |         |
|------------------------------------------------|---------|
| Diamond Drilling (feet) . . . . .              | 12,279  |
| Development Drifts and Raises (feet) . . . . . | 6,502   |
| Ore Mined (dry tons) . . . . .                 | 102,334 |
| Ore Milled (dry tons) . . . . .                | 32,344  |

|                                                            |           |
|------------------------------------------------------------|-----------|
| Ore Shipped Tacoma (dry tons) . . . . .                    | 41,775    |
| Ore Shipped Granby (dry tons) . . . . .                    | 28,215    |
| Table Concentrates Shipped Tacoma (dry tons) . . . . .     | 2,511     |
| Flotation Concentrates Shipped Tacoma (dry tons) . . . . . | 1,614     |
| Precipitates Shipped Selby (tons) . . . . .                | 13        |
| Bullion Shipped Selby (Avoid. pounds) . . . . .            | 908       |
| Ounces Gold Produced . . . . .                             | 127,827   |
| Ounces Silver Produced . . . . .                           | 4,474,367 |
| Ore Broken, 1922 (tons) . . . . .                          | 163,094   |
| Broken Reserve December 31, 1922 (tons) . . . . .          | 73,000    |

"A conservative estimate of the general average of the 73,000 tons broken in stopes as at December 31, 1922, is: .72 ounces gold and 32.0 ounces silver per ton. With gold figured at \$20. per ounce and with silver at 65c this represents a gross value of \$35.20 per ton.

"A conservative estimate of the assured and probable unbroken ore to the present bottom level of the present mine workings is 300,000 tons, averaging .71 ounces gold and 27.0 ounces silver per ton. With gold figured at \$20. per ounce and with silver at 65c this represents a gross value of \$31.75 per ton.

"The orebodies of the Premier within the area of the present workings have maintained their widths to the present bottom level and in fact have widened somewhat, the average width in the bottom level being around 15' and with a length, as far as opened up, of approximately 500'. The average value of the ore has, however, dropped to a milling grade on the bottom level, the value there being approximately .32 ounces gold, 5 ounces silver and although no development other than by diamond drilling has been done below the bottom level, six diamond drill holes, cutting the orebody at various points to a depth of about 100' below the bottom level, have shown a continuance of approximately the same average grade.

"The foregoing tonnage estimates do not represent the total probable tonnage from the Premier property, but refer to the total probable tonnage within the limits of the present mine workings. There is some 600' of unexplored ground to the eastward of the present mine workings and along the same ore zone. Also there are possibilities along the southwestward of the same zone, beyond the present mine workings as well as the possibilities of the vein, with the northwesterly strike and of the various surface showings elsewhere upon the Premier property, some of which, such as upon the Pietou and Cascade Falls No. 8 claims, have been previously mentioned.

"It is desired, however, to make clear to all the stockholders that the very high grade ore—due doubtless largely to secondary enrichment—within the limits of the present mine workings, does not, judging from results of development work to date, live down much, if any, below the point at which the third level is now being started, about midway between the second and the bottom or fourth level, this No. 3 level being approximately 600' vertically below the surface.

"Should the southwestern trend of the Premier ore bodies, beyond the present mine workings be found by further development and exploration to carry commercial orebodies, it is possible that these bodies may show high grade ore at points below the present bottom level, due to the surface contour, the ground sloping toward the southwest, and upon the south-

western trend some 2,000' within the limits of the Premier's property, remains as yet unexplored."

In addition to the above report from Mr. Guess, there is included a balance sheet, a summary account, a property map, and a plan and longitudinal section of the mine workings.

The balance sheet shows, against capital of \$5,000,000 and current liabilities of \$1,142,613, a surplus of \$1,246,829; cash and other current assets, \$1,590,827; mining property and equipment valued at \$4,274,781; and \$129,454 invested in B. C. Silver Mines stock. The sum of \$2,688,277 was written off during the year for depreciation and depletion—over half the sum of the capital stock.

The summary account shows total earnings from ore, \$4,782,885, at an operating cost of \$1,022,506, leaving total net earnings of \$3,760,605. From this is deducted \$2,321,149 for administrative expenses, taxes, depreciation and depletion, and \$65,818 for profit and loss deficit, leaving as balance available for dividends, \$1,373,637. Administrative expenses were \$6,886. By adding the balance available for dividends and return of capital through the amounts set aside for ore depletion and depreciation to the extent of \$1,399,488, the total of the four dividends paid during the fiscal year is reached as follows:

|                           |           |
|---------------------------|-----------|
| March 30th, 1912. . . . . | \$515,625 |
| June 29th, 1922. . . . .  | 757,500   |
| Sept. 29th, 1922. . . . . | 750,000   |
| Jan. 3rd, 1923 . . . . .  | 750,000   |

\$2,773,125

The longitudinal section of the mine workings indicates that almost all the stoping in the mine has been done above No. 2 tunnel, 400' below the outcrop. No. 4 tunnel, 400' below No. 2, has afforded access to the mineralized zone at this depth. No. 3 tunnel between 2 and 4, is now being driven, as Mr. Guess mentions above, to tap what is judged to be the bottom of the high grade shoots.

A profile of the 12-mile tramway suggests the difficulties that attended its construction.

#### POSSIBLE ORES OF POTASH AND ALUMINA

Alunite, or alumstone, a hydrous sulphate of aluminium and potassium, contains in its pure state 37 percent alumina and 11 percent potash. The most extensive deposits known are those near Marysville in Utah, where several million tons have been determined. The mineral is a potential source of both potash and alumina, and is amenable to comparatively simple treatment.

Potash feldspar (orthoclase and microcline) which occurs in abundance in several parts of Canada, contains in its pure state 18.4 percent alumina and 16.9 percent potash, with a combined potential value at present prices slightly below that of the same constituents in alunite. Should an economical process for resolving potash feldspar into its constituent parts be found, the comparative accessibility of some of the Canadian feldspar deposits will put them in a favorable position for manufacture.

Anorthite (lime feldspar) contains in its pure state 36.7 percent alumina, the remainder being silica and lime. Large deposits of this mineral are available in Canada. It is possible that some simple process might be found whereby this alumina might be made commercially available. The minerals containing potash in addition to alumina are, however, at present in the more favourable position for manufacture.

## FELDSPAR SPECIFICATIONS

A special committee of the American Ceramic Society has drafted and submitted for discussion provisional specifications for commercial feldspar.

The Committee's draft is instructive, but somewhat sketchy and incomplete. Preliminarily attention is called to the fact that feldspars of definitely different composition and of definitely different grinding characteristics are in use. "The consumers" it is stated "are a unit as regards specifying the characteristics of the spar they purchase. As might be expected, the producers see many difficulties in the way. However great and real these difficulties are, they must be surmounted to the end that the industries which give the spar its value may enjoy a greater measure of freedom from uncertainty and consequent loss."

### Specifications for Feldspar for Manufacture of Whiteware

1.—**Sampling**—Directions are given that, in sampling carload lots, equal amounts should be taken from at least five different points in the car; no two samples being taken within five feet of each other. In sampling from a bin, five separate samples shall be taken from different portions of the bin and not more than two from the same level. The total sample shall not be less than ten pounds.

(COMMENTS.—Obviously these directions are intended for the consumer rather than for the producer. I suggest that there is always danger in sampling the surface of carload lots. What should be insisted upon is well-timed sampling during the process of loading and during the process of unloading. In no other way may the samples of producer and consumer be fairly considered as mutually checking each other. I also should place the minimum weight limit of a representative carload sample at fifteen or twenty pounds. Ten pounds is too small for safety. In the case of sampling bins it is much easier and more practicable to sample the feldspar when it is being put in the bin.

The subsequent directions for handing and quartering the sample are not sufficiently explicit as to crushing before quartering.)

2.—**Chemical Composition** — Specifications as to chemical composition are based wholly upon alkali content. They are as follows:

| Grade  | K <sub>2</sub> O% | Na <sub>2</sub> O% | CaO. | MgO%      |
|--------|-------------------|--------------------|------|-----------|
|        | above             | below              |      | not above |
| A..... | 10%               | 3.6%               |      | 0.75%     |
| B..... | 9%                | 3.2%               |      | 1.00%     |
| C..... | 7.8%              | 2.8%               |      | 1.00%     |
|        | not above         | not below          |      |           |
| D..... | 3%                | 7%                 |      | 1.00%     |

(COMMENTS.—It is to be regretted that iron content is not included in this table. A rough indication of the maximum limits acceptable for various uses would be instructive. However, this is a matter fraught with many perplexities and complications. The state in which the iron content is found has much to do with the acceptance or rejection of feldspar. This also has an important bearing upon the requisite fineness of grinding. No doubt this will be fully dealt with at a later date; but, in the opinion of the commentator, it would have been well to have touched at least generally on this important feature here. Again, there seems to be a tendency to consider the whole matter only from the point of view of the consumer.

As the consumer already has too much latitude, this tendency must be corrected.)

3.—**Physical Properties and Tests**.—The question of colour and specking is left open to agreement between vendor and vendee.

Directions for testing the fineness of grain in ground material, for determining moisture content in ground material, and for determining fusion behaviour, are given.

COMMENTS.—The only item in this group of specifications that touches directly on the producer is a clause stipulating that shipments shall be made in clean, closed cars. The right is reserved to the purchaser to reject and return the shipment if it be not up to specifications in every respect. It is well to reiterate the fact that specifications will be only a source of trouble and dispute if the producer is not actually helped and safeguarded by them. They can also be safeguards to the consumer. But the consumer does not need protection in the same sense in which the producer needs it. Therefore it will be desirable to draw up explicit directions for the producer so that he will be able intelligently to meet the requirements of each branch of the trade. Simple and easily applied precautions taken before and during the loading of shipments from the quarry will be the best form of insurance.)—J. C Murray.

## CANADIAN PRESIDENTS OF A. I. M. E.

In the March 16th issue of the "Journal" it is said that Mr. E. P. Mathewson is the second Canadian-born president that the American Institute of Mining and Metallurgy has had. This is not correct as he is the fourth Canadian-born among the forty-four that have held office in the Institute since it was founded in 1871.

Of the four, the first to be elected to the office was Richard P. Rothwell "born May 1, 1836, at Oxford, Upper Canada (now the Province of Ontario)." He was also one of the founders, if not the real founder, of the Institute, as the following quotation from the biographical notice in the Transaction shows; "Yet when I say of him that he was one (and in many respects the most influential—I have reason to believe that the plan originated with him) of the three founders of the Institute; that he practically created, or, at least, developed to its full strength and scope, the 'Engineering Journal,' as the recognized organ of the technical practice and the business interests of mining and metallurgy; and that he conceived and successfully maintained the colossal undertaking of that annual cyclopaedia, the 'Mineral Industry,' I say enough to indicate for him a foremost place among the leaders of professional progress." In 1872, 1873 and 1877 Rothwell was a vice-president of the Institute, "but it was not until 1882 that, without any suggestion on his part, he was unanimously elected president." Rothwell died April 17th, 1901.

Dr. James Douglas, president of the Institute 1899-1900, was born in Quebec city in 1837 and passed away in 1918. His work and the great influence he exerted in the metallurgical world, especially what he did to overcome "secrecy in the arts," is well known to most readers of the "Journal." It may be added that during Dr. Douglas' presidency a joint excursion was made, from the city he loved so well, Quebec, by the American and Canadian Institutes to the mines and metallurgical works of Nova Scotia.

Mr. David W. Brunton was president of the Institute 1909-10. The following biographical notes concerning Mr. Brunton are taken from Mr. T. A. Rickard's "Interviews with Mining Engineers" that were published in the "Mining and Scientific Press" but have since been collected and issued in book form. Mr. Brunton was born at Ayr, Ontario, Canada, in 1849, and began his engineering career in Toronto. "In the first place, Mr. Brunton has been accepted as a leader among men, having been president of the American Institute of Mining Engineers. To this mark of distinction we venture to add the statement that in accomplishment and reputation he stands second to no mining engineer in the English-speaking world."

Since the fourth president, Mr. Mathewson, is so well known among us it is unnecessary to comment on his career or characteristics. He will be seen at his best the coming summer leading the cohorts of the American Institute on the excursion to the great triumvirate—Sudbury, Cobalt and Porcupine—to Kirkland Lake and elsewhere in Ontario, to the asbestos area of Quebec, and to his native city where old Mount Royal early smiled on the infant Mathewson.

W.G.M.

## LETTERS FROM READERS

### Argonaut

To the Editor,  
Canadian Mining Journal,  
Sir:—

The virulent and unwarranted attack upon Argonaut Gold, Ltd. made in an editorial in your issue for March 16th, calls for notice and for prompt denial by people who really know the property.

It is impossible for people who know your own literary style to assume that this editorial came from your pen; rather it bears the imprint of a mind that has been grievously disappointed in its endeavor to levy a contribution from the Argonaut treasury.

As the son of one of Canada's most learned chemists, and a graduate of Queen's, you must know that the presence of chalcopyrite in the ore is no unsurmountable obstacle, and that it does not "make the extraction of the gold difficult and expensive." The metallurgical treatment of this ore was clearly worked out by the writer in the old mill (subsequently burned down) during the summer of 1919. Since copper and its oxidized compounds are great consumers of potassium cyanide, they must be removed before cyaniding the ore, and their removal is neither "difficult" nor "expensive."

The article is simply full of misconceptions regarding the property of Argonaut Gold, Ltd., and it should be corrected; this the writer is able to do since he is primarily responsible for the acquisition and development by Argonaut of the old "Huron" property. His first examination was in November 1918; he spent 6 months in 1919 on the property, starting the development along the present lines, and remained "au fait" with all the development down to and beyond the 350-foot level. Of the 500-foot level he cannot write personally, since that work was done after he resigned as Consulting Engineer.

Your editorial statement that "All the evidence available indicates that the mine management will have its hands full paying working expenses and interest on the small amount of capital invested in mine and mill" simply shows that your informant is particularly poor in acquiring evidence, and surprisingly ignorant of values and ton-

nage as developed at the Argonaut. He may, perhaps, belong to that ancient class that still believes "Where ignorance is bliss 'tis folly to be wise"—but his ignorance does not excuse your editorial pencil.

As to there being "only a remote chance of there ever being a surplus for the payment of dividends" the public must take this statement as merely a personal one; time, limited to the balance of the year 1923, will prove him a liar or a true prophet.

The average value of the ore on the first or 85-foot level is \$14.00; the average value of the ore on the 200-foot level is \$15.35; the average value of the ore on the 350-foot level is \$20.00 per ton. These figures are a matter of personal knowledge to the writer; the values obtained on the 500-foot level are not of personal knowledge, but there is no reason to question the honour, or probity, of John W. Morrison, Supt. who reports them to be in excess of \$25.00 per ton.

Now the published statements of the companies operating in Kirkland Lake District show that the total costs or operating expenses at the mine (excluding head or city office expenses) run about \$6.00 per ton; since Argonaut has to concentrate its deleterious copper and remove it before cyaniding let \$1.00 per ton be added. With a cost of \$7.00 and a lowest production of \$14.00 how does your remarkable informant, Mr. Editor, deduce that from a profit margin of \$7.00 per ton "there is only a remote chance for the payment of dividends?"

The paragraphs which refer to "squeezing out" any shareholders," to "re-organization of the Company," to "running a bluff" and similar phrases (which only show a remarkable control of verbiage) do not deal with facts.

The writer can say positively, that there has been no re-organization; that none of the extra million shares added to the capital will be put on the market; that the directorate instead of "running a bluff" have been careful and have conserved all the interests of the shareholders; that your informant is invited to specifically state in what way the action of the directorate has been wrong.

The writer was connected with the opening and development of this mine beginning in the Spring of 1919. To some of your readers he is a man who has never been accused of optimism,—rather the reverse. But with the amount of unusually high-grade ore that is now opened on the Argonaut, and with the management obtaining on the property at the present time, it is the duty of someone to correct the exceedingly false impression intended to be conveyed by your article, which is entirely unworthy of the past history both of the "Canadian Mining Journal" and of yourself. I may add that I hold no shares in Argonaut myself.

John E. Hardman

Montreal

## CORRECTION

In the review recently of the book "Briquetting," by Alfred L. Stillman, the address of the publishers, the Chemical Publishing Co., was given as Scranton, Pa. This should have been Easton, Pa.

Afghanistan is one of the few countries in the world without railways. A contract has been let lately to an Italian firm for a weekly motor service for passengers and freight between Peshawar, in northern India, and Kabul, the capital of Afghanistan.

# THE NEW NORTHLAND

A DESCRIPTION OF PART OF NORTHERN ONTARIO AND TWO OF ITS INDUSTRIAL PIONEERS

(The following is extracted from a volume "The Garden City Press", by J. J. Harpell, which has just been published. The object of this volume is to describe the activities at the Garden City Press at Ste. Anne de Bellevue and Toronto, and the objects towards which these activities are directed. One of the principal objects is to stimulate and aid the rational development of our national resources of all sorts, and the succeeding paragraphs serve to outline the possibilities of development that these resources offer in one corner of Canada.—Ed.)

Before the advent of the railroad, all settlement and hence all industry and commerce were confined to a narrow strip of land a few miles wide lying along the shores of navigable waterways. But today the railroad is the artery that carries life in the form of industrial and commercial activity to wherever potential prosperity is to be found.

The first railroads to be built in Canada all ran east and west, but of late they have been pushing farther and farther north into Northern Quebec, Northern Ontario, Northern Manitoba, Northern Alberta and Northern British Columbia. In each case these roads are opening up new fields and planting industries upon newly discovered resources.

To take one example: the end of steel of the Temiskaming and Northern Ontario Railway which started but a few years ago from North Bay is now thirty miles north of Cochrane and within one hundred and forty miles of James Bay. In less than two more years one may leave Toronto or Montreal any evening and within thirty hours be bathing in the salt waters of this great inland sea.

## Two Large Pioneer Plants

At Iroquois Falls, this railroad has planted the Abitibi Power and Paper Co., already the largest individual pulp and paper mill in the world. Every morning except Monday a train of from twenty to twenty-five cars of newsprint leaves this mill and travels as a full newsprint train to North Bay where it is broken, part of it going west to Chicago and part continuing south to New York. The trip from Iroquois Falls, which is within two hundred miles of James Bay, to New York is made by freight in forty-eight hours.

A few miles west of Iroquois Falls the T. and N. O. Railway has opened up what is likely to become the greatest gold camp of the continent. It is only a few years old, yet its total production up to the end of 1922 was over one hundred and ten million dollars. The output for the year 1922 was about twenty millions of which one mine, the Hollinger, produced twelve millions which output makes it one of the largest gold mines in the world, if not, indeed, the largest.

About one hundred and seventy-four miles farther south the T. and N. O. Railway is responsible for the development of the Cobalt district, which up to the end of 1922 had produced over two hundred and fourteen million dollars in silver and cobalt. When

to these figures, is added the one hundred and seventy million dollars' worth of nickel and copper already produced by the mines in the neighbourhood of Copper Cliff, it will be seen that the mineral wealth already produced by New Ontario amounts to about five hundred million dollars.

The Hollinger Mines Ltd. and the Abitibi Power and Paper Co., Ltd., which are only two of the many industries that are already established in New Ontario, provide fine examples of the national value of successful men and at the same time indicate the magnificent opportunities in the most outlying areas of Canada that await those who will prepare to develop them by giving some attention to organizing their careers along the lines of self-study, intelligent and earnest work and reasonable economy.

Viewing the situation as it is from the **Garden City Press**, industries are but monuments to the work of successful men and women. Without men and women with the will and perseverance to study, work and save, there would be no progress. No matter how rich may be the material resources of a country they remain dormant until out of the intellectual resources emerge men and women with the foresight, energy and means necessary to their development.

## N. A. Timmins — a Pioneer

The town of Timmins, with its population of twelve thousand people and the roar of the stamp mills scattered round about that are busily engaged in pulverizing the ore for the concentration of the gold it contains, had its origin in the minds of a small group of men and owes its development to their direction and supervision. These men were the boys of but a few years ago, with no greater advantages than any boy of today possesses.

Mr. N. A. Timmins, after whom the town is named, is President of the Hollinger Mines Ltd., — the largest individual gold mine in the world. For the year ending December 31st, 1922, this company had a gross revenue of \$12,824,608.25, and a net profit of \$6,478,604.12. By the casual observer Mr. Timmins' great success might be credited to a streak of good luck. But this is not the case, as a review of his life's work will show.

Mr. Timmins was born in Mattawa, Ontario, which at the time was little more than a lumber camp. His father was a store keeper and lumber merchant. After a few years in the public school of his native town and four years at St. Mary's College, Montreal, he entered his father's business as clerk at the age of sixteen. Shortly afterwards he and his brother opened a branch of the business at North Bay, Ontario.

In studying the future possibilities of his business Mr. Timmins early began to realize that as the country around North Bay and Mattawa was not particularly suited to agriculture, once the timber was taken off, much of its future would depend upon the discovery of valuable mineral deposits, which then seemed

quite promising, due to the recent discovery of rich copper and nickel deposits at Bruce Mines and Copper Cliff.

All his spare time was spent in studying mining and all his spare cash in prospecting and in the development of promising discoveries. For fifteen years he continued to put money into the ground without getting anything out. But since this process was accompanied by intelligent observation and study, including a correspondence course, and attendance at instruction classes conducted by itinerant lecturers sent out from the School of Mines at Kingston under the supervision of Dr. W. L. Goodwin, then dean of that institution, Mr. Timmins was securing the best kind of education for a mining career, and one that was bound to bear fruit in time.

As a result, he was one of the first to appreciate the value of the initial discovery made at Cobalt, Ontario. He acquired a quarter interest in the LaRose mine, and directed the first shipments of ore made from that property. When the first two cars of ore were ready to go forward in the spring of 1904 the syndicate of which Mr. Timmins was a member had difficulty in negotiating a loan of five thousand dollars, required to pay wages and freight to the smelter.

But these two cars netted them forty-eight thousand dollars and laid the foundation of their financial independence.

When in 1911 Bennie Hollinger and John McMahon offered for sale the claim they had staked in the Porcupine District, Mr. Timmins was not slow to appreciate its value even at the price of nearly a quarter of a million dollars. He and his associates afterwards purchased several of the adjoining claims which go to make up the property owned by the Hollinger Mines Ltd.

Up to date this property has produced nearly sixty million dollars in gold, earned over twenty-eight million dollars of profits, and paid over eighteen million dollars in dividends.

The contribution which the successful career of Mr. Timmins has made to Canada through the part he has played in the development of her mineral resources provides another fine lesson that should not be overlooked. He has always been interested in mine development for its own sake, and much of the money made thereby has been used for further development. Neither in the days of his financial adversity nor when he was becoming financially independent did he try to gain an advantage by unloading a worthless mine on the public. He has stuck to sound and legitimate development and steered clear of wild-cat promotions. Gambling or fraudulent methods seldom finds a place in a successful career. They tend to pull down and dissipate those who have anything to do with them rather than build up and strengthen.

#### The Rise of F. H. Anson and Abitibi

In like manner the model town of Iroquois Falls and the adjoining communities of Little Canada and the Wye, with their four thousand inhabitants, as well as the mill and hydro-electric power plants of the Abitibi Power and Paper Co. Ltd., around which they have grown up, owe their existence to the foresight, intelligent direction and means of Mr. F. H. Anson founder and President of the above-mentioned company.

Mr. F. H. Anson came to Canada from the United

States in 1901 equipped with an education that included the study of law and engineering, with experience in railroading and with a thorough knowledge of the flour milling business. After nine years spent in perfecting the Ogilvie Flour Mills he sought a new outlet for his energy and ability. A thorough canvas of the industrial possibilities of Canada convinced him that the enormous resources of the Dominion in forests and waterpowers offered the opportunity he was looking for. His choice of the site at Iroquois Falls came about in a curious way.

As so many others have done, he agreed to grub stake two young prospectors who wished to look for silver in the region north of New Liskeard, which, at that time, was the end of the steel of the T. and N. O. Railway. After weeks of unsuccessful search, they were told of gold discoveries recently made in the vicinity of Lake Abitibi, so on they went. They were greatly impressed with the fine timber encountered in that north country and reported it to their benefactor as opportunity offered. Then followed data on Couchiching Falls and Iroquois Falls. Mr. Anson recognized this as the combination he was looking for and had surveys and cruises made, although there was no railway within a hundred miles of the place.

When the Transcontinental Railway was built and the T. and N. O. extended to meet it at Cochrane, Mr. Anson had accumulated sufficient means to make a start on the establishment of a pulp mill. As he began to build and finance his undertaking he found it possible to get sufficient capital to go the whole distance and constructed a well balanced pulp and paper mill on a large scale. The value of the present annual output of this mill is over ten million dollars.

Mr. Anson's own training, experience and habits have enabled him to organize effectively and to pick dependable men for responsible positions. His opinion is that education should fit a person for a job rather than for *some* job. This is exactly what "study in work" does as compared with "study in school."

#### The Great Clay Belt

From New Liskeard north to the shores of James Bay, the Temiskaming and Northern Ontario Railway traverses the great clay belt of Northern Ontario and Quebec. This belt contains over twenty-five million acres of potential farms where the able and willing worker can begin with little or no capital, make a home and gain financial independence in a comparatively short time, as many have already done. This belt will eventually be one of the important dairying and stock raising districts of the Dominion. Meadows and pastures in clay remain for years without reseeded. To homestead a bush farm requires little capital and provides work throughout the year—farming and clearing the land in the summer and lumbering and caring for live stock during the winter. It also provides much of the material required for buildings and fences.

Most people think of the country around James Bay in terms of icebound regions in the winter and muskeg in the summer, fit only for breeding grounds of wild fowl such as geese and ducks. This is far from being a true picture. The height of land or the breast-bone of the North American continent lies but a few miles north of Lake Superior, runs directly east to a point a few miles north of New Liskeard and then turns north-east and runs in a course parallel with the St. Lawrence River. From this high ridge where the

temperatures are necessarily extreme, the land with undulating topography slopes down for two hundred miles to the south end of James Bay where, by reason of the lower altitude and the modifying influences of that great inland sea, the temperatures are more moderate and crops less subject to frosts during the early autumn. From reliable accounts cereal and vegetable crops are less likely to damage from frost at Rupert House and Moose Factory than they are at New Liskeard or Cochrane, where thousands of successful farms are already well established.

This fine wooded watershed of land which lies like the rim of a saucer two hundred miles wide around the end of James Bay is traversed by a number of mighty rivers, notably the Albany, Moose, Harrieanaw, Nottaway, Rupert and Eastmain (the Missinaibi, Matagami, Abitibi and French are tributaries of the Moose). In two hundred miles these rivers drop from an altitude practically the same as is covered by the Mississippi in twelve hundred miles with the result that the product of erosion is carried to the mouth instead of being deposited en route resulting in floods and shifting courses to the river beds. These rivers have worn their courses to the bottom of the clay so that in places the river bed is from fifty to sixty feet below the surface of the surrounding country, thus making hydro-electric dams easy of construction. It is estimated that there are over two hundred excellent water powers in this area of which only six have already been developed.

#### A Picture of James Bay Area

With this general outline, let me present a picture of conditions as given to me a few weeks ago by the Ven. Archdeacon Woodall of Porquis Junction, Ont., who has lived with his family for fourteen years at Rupert House. During this time he visited practically all places along the shores of James Bay and made many excursions up the larger rivers for several hundred miles.

Rupert House is situated at the mouth of the Rupert River about three hundred miles farther north than Montreal and about eight hundred miles farther south than the Hudson Bay entrance to Baffin Straits. The tide at Rupert House averages about four feet. So shallow is the southern end of James Bay that the distance between the water line at low tide and high tide at many places is as much as seven miles. The bottom is clay and so hard that a man may walk anywhere without difficulty as he often has to do when his boat is stranded as the tide is going out. When dikes are thrown up, as they could be at little expense, much of this land will be easily put under cultivation. From the water line to the tree line there are several miles of prairie land where the grass grows luxuriantly. In places this prairie land is as much as twenty-five miles wide. Hay is annually cut in these meadows for the cattle kept at Rupert House. This shoal land in places is formed into islands that are never submerged. In order to save fencing, the young cattle at Rupert House are pastured on one of these islands. They are taken over just before the ice breaks up in the spring, which is generally towards the end of April and brought back after the ice has taken in the fall, which is towards the end of November or the forepart of December. When asked how he could live there for so many years without medical attendance, Archdeacon Woodall replied that it was something

they seldom had occasion to think about. They lived well on dairy products, vegetables and fish, led an active life in the open and seldom suffered from physical ills. He was inclined to attribute much of this healthy condition to a regular diet of fish. An excellent quality of fish is easily procured by staking nets when the tide is out and gathering the fish in pail fulls from the nets after the tide has risen and receded.

The picture which Archdeacon Woodall left with me was of a country which eventually would be very similar to the excellent and well tilled agricultural areas lying behind the dikes around the shores of the Zuyder Zee in Holland.

#### SOUTH AFRICAN ASBESTOS

The asbestos deposits of South Africa, the world's second largest producer, are described briefly in the "South African Mining and Engineering Journal" of February 3rd. The working mines are widely scattered throughout Cape Colony, the Transvaal and Southern Rhodesia. Blue asbestos, or crocidolite, comes chiefly from Cape Colony. It is brittle, but the fibre is long. A new variety, amosite, a ferrous amphibole, has been mined recently from deposits in the Transvaal. It has unusually long fibre, the length from one deposit averaging six inches, and is said to be useful for spinning. Chrysotile asbestos also is obtained in the Transvaal and Natal, a new and important district being now in operation at Kaapsche Hoop, near Barberton, where unusually long fibre, much of it over an inch in length, comprises quite ordinarily 30 to 40 percent of the rock quarried. The fibre occurs here in parallel seams, giving a ribbon structure. Another important Transvaal deposit is the New Gloria mine, near Messiva, which is compared with the quarries at Danville, Quebec.

The larger part of the South African asbestos, however, is derived from Southern Rhodesia. It occurs in widely separated districts, a number of which already have become important producers in spite of transportation difficulties. The Shabani and Mashaba districts are at present by far the most important producers, both in Rhodesia and in all South Africa.

The South African asbestos trade had a decided setback during the recent slump, but now it is improving gradually. The production during 1922 was valued at £80,230, against £103,067 in 1921 and £114,195 in 1920. It has thus a long way to go before it approaches in value the Canadian production. Transportation charges from South Africa to the chief centres where it is used will always militate against its use; but the gradual extension of the railways to the asbestos areas will make South Africa a competitor of growing importance with the Quebec field.

The value of the new aluminum produced in the United States in 1922, as reported by the Geological Survey, was \$13,622,000, an increase of about 25 per cent. over the value in 1921. During the first half of the year domestic aluminum was quoted at 20 cents a pound for 99 per cent. grade; in August the price was raised one-tenth of a cent a pound, and on the passage of the tariff act it was raised to 23 cents a pound, where it remained during the rest of the year.

The manufacture of Portland cement in the United States during January and February of this year exceeds the production in the corresponding months of 1922 by 84 and 83 percent, respectively.

# THE IRON ORE PROBLEM

BY WM. A. DOWLER

(The following is the fifth of a series of articles on iron ore by Wm. A. Dowler, K. C. one of the group of residents of Port Arthur, Ontario, who have studied the iron ore problem from various angles in an endeavour to make useful the great quantities of potential ore that lie tributary to their city. The first four articles dealt principally with the occurrence of iron ore in the adjoining part of the United States, and have been published in the "Financial Post." This fifth article is to appear in that paper also. — Ed.)

## What is the Iron Ore Situation in Ontario Today?

The answer is that, notwithstanding the fact that geological knowledge and deductions assure us of the presence of more iron-bearing rocks and a greater area of iron formation in Canada than in the United States, and that surface explorations have established conclusive proof thereof, nevertheless not a single ton of iron ore is being mined in Canada today and the whole iron and steel industry of Canada, and Canada's whole domestic and foreign trade in iron and steel deposits, rests upon about ten million dollars worth of foreign ore, imported chiefly from the United States, and upon many million dollars worth more of iron and steel imported from the same country. Moreover all increase of iron and steel production in Canada depends upon the same source for raw material, the market price of which to Canada is largely controlled by Canada's chief competitors in the manufactured products of such raw material.

**What is to be done about such an impossible situation? Shall we continue a policy of drift and the role of "Micawber?"**

With the exception of three serious attempts, at the Antikokan mine, at the Helen and Magpie Mines and at Moose Mountain, separated from each other by hundreds of miles, we Canadians have done little but drift.

## What is the result of this Policy?

During the last thirty years the Mesabe and Cuyuna ranges in Minnesota have come into being. Iron mining has become established on these ranges on such mammoth foundations of plant, equipment and organization; the transportation of the ore from the mine to the boat has become so well organized and such effective equipment has been provided therefor; such extensive and far-reaching organizations have grown up, entrenched behind interlocking directorates and affiliations that so dominate the supply, price and distribution of the ore mined; that a very imposing wall has been built up during these thirty years against any beginners in the iron ore business in Canada.

Again the business of Canadian furnaces has been so founded on certain United States grades and blends of ore that a beginner in Canadian ore would find poor encouragement in the limited Canadian market. On such a small share of the Canadian consumption as he could hope to secure he could not begin to install the mining equipment or organization

that would enable him to compete as to mining cost with the Minnesota mine, and would enable him to ship at a competitive cost of transportation, since on shipments for the Canadian Market alone the transportation companies would not care to afford facilities and rates corresponding with those in the United States.

Suppose, for instance, an individual or group of individuals spent the time, effort and money to demonstrate the existence of a shipping quantity of Canadian ore in one deposit and sought to secure a purchaser or to interest capital to mine and move that ore. The two questions of mining cost and cost of transportation face him. Suppose he asks the railroads to furnish him with a rate and facilities corresponding to those that can be secured at Duluth and Superior. The Canadian railroads have no such facilities — the facilities at Duluth and Superior cost millions. How can the railroads be expected to furnish such facilities without an assurance of continued tonnage on a scale to furnish long-continued revenue? How can this assurance be given on the basis of ore to be shipped to the limited Canadian market which may be available?

If, during the last thirty years, such conditions have become established and now constitute hills of difficulty against a present attempt to create a Canadian supply, will another period of years of inaction and indifference lessen these hills of difficulty — will not the number and height of the hills on the contrary increase?

And these are not the only hills of difficulty.

If one ventures to mention the subject of iron ore he is told Canada has none worth while, that the United States Steel spent millions in trying to find ore and gave it up as a failure; and this statement, together with some disappointments that have been met by others is regarded as setting the question for all time. In fact, so completely has this motion taken hold of everybody that it has become a sort of settled creed amongst the United States interests, the Canadian furnace people, Canadian business men and Canadians generally, that Canada has not ore worth while.

## Wherein lies the justification for this organized pessimism?

The United States did not open up any of the Minnesota ranges, neither did any of the big interests. Both the United States Steel and Pickands, Mather & Company went into the Cuyuna range and spent large sums and abandoned the field, and yet the Cuyuna range has proved its value and is a heavier shipper today than the original Vermillion range and is likely to continue to be such, even though the ore has to be explored for at great depths, with no surface indication to guide the explorer.

As an illustration of why no person has a license to make or believe the statement that we have no merchantable ore, take the course followed with a single forty acres on the Mesabe Range. If the driller in putting down five or six holes across the forty acres strikes an underground deposit of taconite or iron

formation, not ore, he immediately proceeds to cross-section the whole forty acres with holes comparatively close together, to find if possible a deposit of ore in the body of taconite discovered. This is intensive prospecting, such as has never yet been conducted on the Canadian ranges.

There is a known range of iron formation along the Port Arthur and Duluth Railway in this district, from Gunflint to the Mattawan River, a distance of over sixty miles and not a drill hole has been put down on it except a few in the neighborhood of Mokenin near the Mattawan where the formation is much folded and disturbed. Has any one license to say or believe there are no mines in this range of sixty miles because shipping ore was not found as a result of a few holes in the extreme end? This range is only one of a half-dozen or more in the Western and Northern part of Ontario, to say nothing of other parts of Canada.

**How are these hills of difficulty to be overcome and the present situation changed for the better?** By affording some special incentive to initiative and enterprise in the utilization of our deposits and the proper exploration of our ranges, and by affording some inducement to Canadian Furnaces to experiment with and use Canadian ore, their commercial use will be assured.

Two large investments, at the Helen and Magpie mines and at Moose Mountain, are lying idle because the concentrated products have not a profitable assured market at present cost of production in their present form. Were it possible by some incentive to start these ores moving in large quantities the momentum would keep them moving thereafter.

Some incentive which would operate as a differential to meet the cost of treating the sulphur in the Atikokan ore and the extra cost of handling at the water front would put that idle mine and the Atikokan furnace into operation.

A sufficient incentive would attract enterprise and capital to the beneficiation of the extensive bodies of low-grade ore, magnetite, hematite and siderite, which are exposed in different places, and which are as high and in some cases higher in iron content than are being utilized elsewhere on this continent and generally in Europe.

But more important and far-reaching still, and probably more certainly, a sufficient incentive would at the present time surely attract men with the initiative, enterprise, courage, persistence and money to carry on proper intensive exploration of the known iron ranges we possess, and to discover others. Just as surface exploration and the discovery of surface outcroppings in many places and over large areas have proved the correctness of geological deductions as to the existence of many large areas of iron formation, the underground exploration of these areas is sure to disclose the assembling at numerous points in these iron formations, of the iron oxides in such concentrated form as to constitute ore-bodies of shipping quality.

**Where should these incentives and inducements come from?**

They should be provided by the Province in the first place, which will ultimately reap the benefit from the added wealth of those parts of the province in which the industry is established. They should be provided by the Dominion in the second place, which will derive the advantage of the increased industry and trade, built on the solid foundation of our own natural resources.

**Whence should additional encouragement come?**

It should come from the iron and steel industry of Canada and the business and transportation interests generally.

**In what form should such latter encouragement come?**

It should come in a readiness on the part of the iron and steel industry and business interests to weigh and consider evidence submitted and on reasonable evidence make reasonable bets on the discovery of shipping ore and on the utilisation by beneficiation of leaner deposits. There should be also readiness on the part of transportation interests to anticipate somewhat the possibilities of ore development in given localities, and on probabilities based on reasonable grounds to anticipate shipping requirements, and to consider and establish rates to encourage the development of traffic in iron ore?

Provincial and federal incentive measures should manifestly be of a general character such as is available to induce and secure all the different activities aimed at and should be based on results, and thus cost nothing unless results are obtained. The offer might remain open for a limited period only and likewise might extend only during a limited period.

The provincial measure should be of a type that will appeal to and attract the activities of the prospector, the developer, and the man with money who can afford to acquire and is willing to take the risk on prospects that appeal to him as suitable to market and transportation conditions.

Such prospectors, developers and men willing to take such risks opened up the Minnesota ranges. We have been waiting for them to do the same with the Ontario ranges; but we have not had, nor have we now, the same drawing conditions, and thirty years of waiting since the first Mesabe shipment finds us farther away than ever by reason of the equipments, facilities and channels of trade being established and entrenched in other quarters.

Should the special incentive, inducement and encouragement indicated be provided, the attention of prospectors, developers and men who can and will take the risks will be secured; the intensive exploration of our ranges will be undertaken; shipping mines of high-grade ore will be opened up, and beneficiating plants will be put into operation; and the situation deplored at the outset of this article will be changed and our heritage of iron ore in the pre-Cambrian area be made to yield up its treasures. Thus will Canada come into her own as an iron ore producer.

Will we Canadians fail to meet the needs of the situation? Surely not.

## RESEARCHES ON COAL

Fine coal dust and moist air quickly increase the hazards of spontaneous combustion, according to Bulletin No. 3, reporting recent coal-mining investigations, and issued by Carnegie Institute of Technology, at Pittsburgh. Another conclusion set forth in the report is that the mixing of fresh coal and old coal does not develop any more heat than that due to the coals themselves when piled separately.

This bulletin is one of a series of four that are now available for distribution, giving in full the findings of research work conducted under the joint auspices of the Carnegie Institute of Technology, the U. S. Bureau of Mines, and an Advisory Board of coal mine operators and engineers. Carnegie Tech employed four Research Fellows for the work, the Pittsburgh

Experimental Station of the U. S. Bureau of Mines provided supervision; and the Advisory Board, which selected the problems, also provided the funds to publish the bulletins. Their issuance marks the first milestone in the serious efforts of the coal mining industry to stabilize the mining business in co-operation with an educational institution.

That most of the alloys available for use in coal mine equipment are corroded extensively by the acid waters in mines was one of the results of tests described in Bulletin No. 4. The corrosion tests on metals and alloys in acid mine water from coal mines were undertaken at the suggestion of an Advisory Board of coal operators with a view of obtaining information as to the acid resisting properties of the various metals and alloys available for use in underground equipment exposed to the corrosive action of acid mine waters.

According to the report, brasses, which contain considerable zinc were corroded rapidly; bronzes containing considerable tin were also corroded, but to a less extent than the brasses; cupro-nickel and nickel-silver alloys were corroded about to the same extent as the brasses. Alloys that were practically unattacked by the acid mine waters include a high chromium steel, two highly alloyed chromium-nickel-silicon steels, a nickel-chromium-iron alloy, and a high-silicon cast iron. These resistant materials possess certain disadvantages for general use in coal mine equipment, such as the brittleness and hardness of the high-silicon cast iron and the relatively high cost of the others. However, these resistant materials should prove satisfactory for use in such pump parts and other equipment where these factors are not a serious consideration.

Thick Freeport coal when carbonized at temperatures around 600 deg. C. will yield 25 to 30 gallons of tar, 8,000 cubic feet of gas, and about 1,380 pounds of low-volatile coke per ton, according to Bulletin No. 1. This conclusion was derived from tests made in a study of "the yield and quality of the gas, oil, and other by-products of the constituents of the Freeport Coal Bed, Pennsylvania." The problem was undertaken at the suggestion of an Advisory Board of coal-mine operators and engineers and conducted under the joint auspices of the Carnegie Tech. Mining Department and the U. S. Bureau of Mines.

Other conclusions set forth in the Bulletin are:

"Bone coal is worth about half as much as the true coal — that is, from the standpoint of gas and oil yields. The distillation residue is not a coke and is of small value, but perhaps could be utilized for special purposes."

"The cannel coal tar is worth perhaps more than the tar from the true coal, and the gas is better, though the yield is only about half that of the true coal. The residue is non-fused, different from that of the bone coal, and lower in ash content."

"Bone coals and cannel coals yield about half as much ammonium sulphate as the true coals."

"Considering the value of thick Freeport coal as a high-temperature by-product or gas coal, it probably would not pay under prevailing economic conditions to carbonise it at low temperature."

A marked variation in the structure of the Freeport coal from the bottom to the top of the bed was found in "a microscopic study of the Freeport Coal Bed, Pennsylvania", according to the report contained in Bulletin No. 2.

According to Reinhardt Thiessen, Research Chemist, U. S. Bureau of Mines, and Anson W. Voorhees, Research Fellow, Carnegie Institute of Technology, the authors of the report, the individual benches of the Freeport bed also vary in composition from bottom to top. At the top of the upper bench is found a coal composed almost entirely of spore-exine-rich attritus, and containing much humic but very little anthraxylon. This concentration of spore and pollen exines, cuticles, and humic matter is so pronounced that in some of the sections this portion of the coal resembles a cannel, and differs from it chiefly in its much more pronounced bedding.

The thick Freeport coal bed was sampled at five mines, suitably situated in the area under consideration. Photomicrographs were made at regular intervals from the bottom to the top of the bed, including the bone and cannel constituents, and a number of the typical photomicrographs are reproduced in this report.

Copies of any of these four reports may be obtained from Edward Steidle, Supervisor, Cooperative Mining Courses, Carnegie Institute of Technology, Pittsburgh.

## COAL SITUATION HOPEFUL

by John Moffatt

Coal is King today, Coal has the floor—and who will put him off? Senator J. S. McLellan, whose early life was spent at the Cape Breton Collieries, rising from one position to another until he became a director of the Dominion Coal Company, in a very carefully prepared and able speech, expounded to the Senate the necessity of making Canadian coal, if possible, bridge the wide gap left by nature in her distribution of the coal fields in Canada. A committee was at once appointed to make inquiry into coal conditions. The House of Commons followed along similar lines, and we can hope that the more extensive use of Canadian coal fields is foreshadowed by the work of these august bodies.

Sir Henry Thornton, in giving evidence before the Senate Fuel Committee stated that the railway rates on coal could be lowered to enable Alberta coal, which is now coming as far East as Winnipeg, to compete with American coal still further east. Nova Scotia coal could at low rates be carried further west than is now being done. Whether Canadian coal can cover the whole territory between the mines of Alberta and Nova Scotia is problematical, and whether Canada can become wholly independent of American coal is doubtful. But with low rates and the changes about to take place, such as the making of coke in the larger Canadian cities and the saving of the by-products, we are evidently on the eve of a new Coal Age in this country. Canada has no great known fields of anthracite, but substitutes can be made. The anthracite coal areas of the United States are being rapidly exhausted, and while for years to come they may maintain an output of 85 or 90 million tons, yet the price will continue to increase as the more accessible areas become depleted, and may reach a figure which Canadians will refuse to pay.

A Scottish professor speaking before one of the Mining Institutes of that country, recently made the

statement that the time is not far off when very little coal in its raw state will be used for domestic purposes, that the by-products of all coal will be extracted and a great waste of fuel now going on will cease.

Professor Deon of Glasgow University, speaking before the students of that city a short time ago on coal research, stated that methods for the production of smokeless fuels had during recent years been the subject of much experimental work in Glasgow and elsewhere. He believed that the corporation of Glasgow now contemplated a great practical advance in this direction—an advance that might mean that in a few years the City of Glasgow would enjoy as pure an atmosphere as was experienced during the unfortunate strike of 1921. He further stated that science was busy with coals that were non-coking and that a process would no doubt be discovered by which they could be made into coke.

President Roy Wolvin, in his report to the directors of the British Empire Steel Corporation the other day, stated that the manufacture of coke for household use is under consideration by his company. This is along the right lines, being both a conservation of fuel, and a substitution of native for imported coal. When the yearly output of the Nova Scotia reaches the 10,000,000 tons set by Mr. F. W. Gray as a maximum, it may by new processes as yet undiscovered have the efficiency of double that quantity.

The inferior coals, such as the lignites, stand to gain much by the changes that follow the extensive experimental work being made on this continent. Thus the value of a grade of fuel now avoided wherever possible will be gladly enhanced, and its uses will become more general.

Economical use, by increasing the efficiency, will go a long way in solving the fuel problem of this and other countries.

## A NEW METHOD OF MEASURING THE FLOW WATER\*

By NORMAN R. GIBSON \*\*

About the end of the first century, Hero of Alexandria first described the volumetric, or bulk, method of measuring the flow of water. He pointed out that it was not necessary to measure the area of the orifice through which the water was flowing but that a pit might be dug and the water allowed to flow into it for an hour by the sun dial, and the volume of the pit filled in that time determined. This method, refined by the use of instruments of precision, remains today the standard.

During the past three years, an entirely new method has been invented by the author, using three fundamental principals developed within the last 250 years; that force is equal to the product of the mass and acceleration of bodies; that the momentary change of pressure in an enclosed column of water is equal to a "constant" multiplied by the momentary change in velocity, when due allowance is made for the compressibility of water and the elasticity of pipe walls, and when the speed of propagation of pressure waves in water is taken into consideration; and that spouting velocity of water is equal to the square-root of the head or fall under which the water is discharged, multiplied by the square-root of twice the gravitational unit.

Velocity heads and friction losses are proportional to the square of the velocity.

Two essential conditions for the new method are: First, the water must flow through a pressure pipe or other closed conduit, and, second, means must be available for controlling the flow, such as a valve or the gates of a turbine at the end of the conduit. In a typical hydro-electric power plant these conditions are fulfilled when water flows out of a forebay into a penstock at the lower end of which is a turbine and generator equipped with hydraulic governor to operate the turbine gates. The new method is particularly applicable to measurement of water for testing efficiencies of hydraulic turbines in hydro-electric power plants.

The principal operation is to obtain a record of the changes of pressure that occur in the conduit when the water therein is brought to rest. Steady conditions of load on the turbine are maintained for several minutes until the flow has become as uniform as possible. When the usual observations of head, power, etc., have been made, the turbine gates are gradually and gently closed so as to shut off the supply of water to the turbine. Immediately preceding and during the closure of the gates and for a short time afterward, there is obtained a record of time intervals and of the changes of pressure that occur in the conduit. This record is obtained by means of the Gibson Apparatus which is connected through the wall of the conduit by a 1-4-inch piezometer opening at any convenient point upstream from the turbine casing. After the closure, when the disturbance in the penstock has subsided, the same apparatus is used to record the static pressure then existing in the conduit. The complete record is called the pressure-time diagram and when properly interpreted is a precise measure of the mean velocity of the water in the conduit at the moment the gates began to close.

In addition to usual equipment for efficiency tests there is required the apparatus for obtaining pressure-time diagrams. It combines mercury U-tube gage, pendulum, camera box, photographic lens and motor-driven revolving drum enclosed in a light-proof cylinder. The U-tube is made with a short leg of glass tubing and a riser of steel tubing, the ratio of the areas of the two legs being such as to limit within the length of the glass tube the displacement of the mercury under changes of pressure. Calibration of this ratio is readily made.

The making of a pressure-time diagram is simple, each diagram being made on a photographic film 11-inches wide by 18-inches long, from which blue-prints are obtained. On the blue-prints lines are delineated, first to determine the end of the diagram, which is readily accomplished by reference to the uniform periodicity of the pressure oscillations which occur after closure of the gates, and, second, to eliminate from the diagram that portion of its area which has been created simply by the recovery of the combined friction and velocity heads of the water flowing in the conduit. The remained of the area is then used as a measure of the mean velocity in the conduit. In this method only the flow actually shut off is measured. Usually the turbine gates are not perfectly tight. This leakage is readily determined and added to the discharge calculated from the diagram.

Measurements at the hydraulic laboratory of Cornell University, in 1920, showed the mean variation from volumetric measurement was less than 0.2 of one per cent, and the maximum variation of any one measurement was 1.6 per cent. Advantages, in addition to accuracy, are brief interruption in operation of power plant, and low cost.

The North Western Railway of India has laid 50 miles of track with a new iron and concrete sleeper, the "Stent sleeper", which is fitted with plugs of creosoted wood to which the rails are attached.

# The Mining Districts

BY THE JOURNAL'S CORRESPONDENTS

## NORTHERN ONTARIO

**COBALT.**—The new shaft of the Colonial is now down slightly over 900 feet, and the contact should shortly be reached. It is proposed to crosscut to the vein, close to the contact, and after drifting for a short distance in the underlying Keewatin, to run an incline raise at an angle of 45 degrees in order to thoroughly prospect both formations.

The Coniagas is meeting with very good results in the development of the Beaver, and several high-grade shoots have recently been opened up. It is understood that the company is negotiating for the purchase of the property from the Beaver Company rather than continue operating under lease, as is being done at present. Under the agreement the Beaver Company gets one-half the profits. The mine has not yet been fully unwatered, and work has not been started at the lower levels, where interesting developments are expected.

During the month of February the Mining Corporation treated 8,481 tons, and produced 71,439 ounces. The costs at the mine were \$47,620, which does not indicate a profit to the company. Very favorable results, however, are being met with in the operation of the Frontier property in South Lorrain, which is operated by a subsidiary of the Mining Corporation. The first real stoping has been started and the new shoot on the Woods vein has been opened for a length of 90 feet, and shows from 5 to 30 inches in width of high grade ore, running 3,000 to 8,000 ounces per ton. It is understood that 1,000,000 ounces has been produced from drifts alone. In order to provide additional tonnage for the mill at Cobalt, the company has an option on the Kerr Lake dump, and is now sampling it. This dump is estimated to contain 75,000 tons.

During the month of February three Cobalt companies shipped 174 tons of ore and concentrates, and the Keeley Mine in South Lorrain shipped 41 tons, making a total of 215 tons, all of which went to the Deloro Smelting & Refining Company. The Cobalt companies shipping were the O'Brien, with 97 tons, McKinley with 44 tons and Larose with 33 tons.

**EXTENSIVE DIAMOND DRILLING.**—Diamond drilling is being used to a greater extent than ever throughout the various mining districts of Northern Ontario, and it is stated that there is a total of 40 drills at work. Most of these are being used in the Porcupine district, where the three big producing mines, Hollinger, Dome and McIntyre, are working 11 drills. The paymaster is also running several drills, and an outfit has recently been started on the Moyer-Bremner property, which as lately been optioned to La Rose. In the new Rouyn gold district of Quebec, 4 machines are already at work, and it is expected that the results of this drilling will have an important bearing on the development and exploration work that will be undertaken there this summer. Several machines are being used in Kirkland and the surrounding district. The Norando Company will shortly begin drilling on its claim in Gauthier township, west of the Northland.

**KIRKLAND.**—On the 900-foot level of the Kirkland Lake Gold, the new ore-body recently developed on the 700, 800 and 1000-foot levels has been intercepted, and the values are understood to be high. It was recently reported that American interests were negotiating for the control of this property, but nothing definite has developed.

At the annual meeting of the shareholders of the Argonaut Gold Mines Limited, in Montreal, the by-laws authorizing the directors to increase the capital from \$3,000,000 to \$4,000,000 were passed. The new stock will not be issued to the public, and will be used to pay off the company's obligations and to acquire additional properties.

**SHINING TREE.**—The Tonopah Mining Company of Nevada has stopped work on the Herriek mine in West Shiningtree. The Tonopah Company has had an option on the Herriek for a considerable length of time, and in addition to deepening the shaft did a large amount of drifting. Values of about \$5.00 a ton were found over comparatively narrow widths, which is not enough to hold out much encouragement in that section, where transportation facilities are poor.

**PORCUPINE.**—The 31st of March will be the end of the Dome fiscal year, and will mark a new step forward in the history of that company. Official figures are not yet available, but it is understood the production will amount to \$4,600,000, an increase of \$1,800,000 over the preceding year, while profits are expected to be \$5.50 a share as compared with \$2.50. The cash surplus over liabilities is approximately \$3,500,000, and broken ore reserves 400,000 tons as compared with 275,000 tons. During the last month or two the tonnage treated has been curtailed on account of the power shortage, but mill heads are reported to be the highest in the history of the company.

**POWER SUIT.**—The suit of the Northern Canada Power Company against the Hollinger is now being heard in the Supreme Court of Ontario. The action arises out of the fact that the Northern Canada Power Company has never had a hard and fast power contract with the Hollinger, and is asking for specific performance in the execution of a contract which it is alleged the Hollinger agreed to sign in November, 1912. The Hollinger entered into a written agreement to sign a contract, but the contract itself has never been completed. The Power Company asks that the Hollinger be required to sign this contract, which calls for the full power requirements for the life of the mine. The Hollinger claims that the Power Company is unable to live up to its side of the agreement, and in support of this points to the fact that the mine is now receiving only 3200 h.p., as against 10,000 h.p. which is necessary to carry on operations at the capacity of the present plant. The mine also proposes to increase the output to 8000 tons per day, which will call for considerably over 10,000 h.p. The Power Company takes the stand that it will make provision to supply the mine if it receives reasonable notice of any prospective increase in consumption. The company states that since 1920 it has received no official or

formal notification of the Hollinger's intentions to increase its operations and power consumption, and also brings out the fact that in 1915 Mr. Percy Robbins, the previous Hollinger manager, wrote the Power Company stating that the Hollinger intended to make enlargements which would call for 6500 h.p. within two years, and that although the Power Company made the necessary enlargements to meet this increased demand that it was not until five years later, in 1920, that the mine was able to use this amount of power.

### NOVA SCOTIA

**THE STEEL WORKERS' UNION.**—The week has been one of sensations, and the workers of the Sydney steel and allied industries had sufficient to stir them up and set them thinking seriously. In an open letter replying to the manifesto of President Roy Wolvin, who outlined the policy of the Steel Company as "the open shop, no recognition of the union, no check off, but an increase of pay to the workmen when the industry could afford it," the officers of the Steel Workers' Union uttered their defi. The tone is arrogant and insolent, the language boastful and threatening. The demand for a fifteen percent increase was cancelled and one for thirty percent substituted. The eight-hour day, the check off and recognition of the Union if not granted, are to be forced. There is no attempt made to hide the "rule or ruin" policy of the Steel Workers' Union.

The press reports state that only one hundred and fifty members were present when this resolution was drawn up, and some people seemed to take comfort out of the fact that the members were few, seeing the total of the workmen employed is about three thousand. Small meetings, however, do not always indicate that the majority will not obey a strike order when it is sent out. A strike is very contagious and the feeling runs like wildfire. The Steel Company seem to realize this and have set their house in order. They have reduced their authorized capital from \$500,000,000 to \$250,00,00 and have captured public confidence. They have taken care to inform the public of the unprofitable state of the steel trade during the year just ended. They have also made it known that prospects are much brighter, and with increased profits the wages of the workmen would be put up. They have likewise given their view of the attitude and actions of District No. 26, United Mine Workers, in Nova Scotia.

**R. M. WOLVIN'S REPORT.**—President Wolvin, in his very able report to his directors and shareholders, shows that both the coal and steel industries of Cape Breton are being much hampered by paid agitators, with no other desire than to wreck the industry. He points out that the check off system had provided funds to put into operation revolutionary propaganda. The responsible officers of the Union, after signing agreements on behalf of their members, publicly declared that the contract signed by them was not binding, on their part, but only binding on the Company. The U. M. W. officials in their official newspaper and on public platforms in Nova Scotia and elsewhere openly justify the destruction of the Company's property by strikers. President Wolvin further stated that "we have reason to believe that money collected by us, for the United Mine Workers through our offices, is being used as the main support for most dangerous newspaper propaganda, not only aimed at the Com-

pany, but for the avowed purpose of overturning established government in Canada."

**A DANGEROUS SITUATION.**—The storm centre for this agitation has shifted to Cape Breton and has reached an acute stage, demanding consideration by all thoughtful and responsible citizens. The movement is apparently more political than economic in its objects, and is causing alarm to all who are interested in the industrial development of Nova Scotia, and therefore demands very serious consideration by the Government authorities both at Halifax and Ottawa.

President Wolvin is right in his statements. The district officers of No. 26, against the wishes of the international executive with headquarters in the United States, are using their funds in an attempt to destroy the industrial system of Canada, especially the steel and coal industries of Cape Breton. Should the Steel Company reach the stage where they will be forced to refuse to collect the check off for the miners, they will be fully justified in that action, and may not be greatly blamed by International Headquarters. Indeed the district has already been accused from this quarter of taking money given to them by the International Treasurer for the purpose of helping them during the late coal strike and saying nothing about it, while at the same time their own funds were used to finance a newspaper openly advocating the destruction of their own international organization. The check off is usually granted on the understanding that the labor organization is a responsible body and as such will loyally fulfil all agreements. If agreements are repudiated by the labor leaders, as is now being done, and business left at the mercy of every new agitator or aspirant for office, why make contracts or give the check off? Why not settle the whole question and be done with it? And while settling it, if it is found that some districts of Nova Scotia are willing to keep their agreements, why not continue to do business with these in the old way? There are many good, right-thinking miners in Nova Scotia who are not in sympathy with the disloyal, unpatriotic Bolshevik propaganda now carried on. They prefer to be true to their agreements, and to the instructions of the international organization they have joined, and if it comes to having to choose between the officers of District No. 26 and President J. L. Lewis and his Executive, they will follow the latter.

**A REBELLION AGAINST TYRANNY.**—Already the locals of Cumberland and Pictou counties have objected to the red Russian methods of their officers and have refused to pay per capita dues to the district. They have advised international headquarters of their action and the cause. If a section of the workmen are so staggered by the extreme action and advice of their own leaders that they revolt, why should the British Empire Steel Corporation not make their protest to the international executive as well as to the Canadian public? Objection might be raised that Canadian industry should not be forced to appeal to American labor organizations against Canadian workmen. But both parties have long ago recognized the American union. The constitution was taken as a basis of recognition of the union and when the principles on which it is found are subverted by a district in Canada, surely the proper thing to do is to appeal to the executive. There justice and fidelity to agreements will be found.

Of course this has to do with the mining only; but the disturbance among the steel workers has been

fermented by leaders of the miners and the lawless turbulent spirit created at the collieries and seen in the late strike at Sydney may again be witnessed if it is possible to bring on another strike. Let us hope that wisdom may prevail at a time when the prospect for a good year so much needed is growing brighter.

### BRITISH COLUMBIA

**PORTLAND CANAL.**—The "Outsider" group of claims, situated at Maple Bay, Portland Canal, British Columbia, which has been acquired by the Granby Consolidated Mining & Smelting Co. and is to be further developed and equipped with surface and underground plant next summer, is not a new property. It was staked years ago and the work of exposing and blocking out the ore, as well as the provision of facilities for mining and shipping it, were far advanced long before the Granby company became interested. For this reason it is not surprising to learn that H. S. Munroe, general manager of the Granby, estimates that there are between 30,000 and 40,000 tons of ore in sight and proven and that, with the construction of adequate docking accommodation, the installation of an aerial tramway, and other such preliminaries, it will be possible to undertake shipments to the Anyox Smelter. Such shipments, it may be stated incidentally, are expected to commence before the end of the year.

There are fourteen claims, including fractions, in the property. Up to the year 1906 a quartz vein had been traced through seven claims running diagonally up the hillside at an angle of 30 to 40 degrees. The principal work was done at the junction of what is known as the "Regina" and "Copper King" claims. At an elevation of 1,100 feet, and 6,000 feet back from the Bay, a main tunnel was run in 300 feet on a well-defined quartz vein, which follows the strike and dip of the schistose country rock, the dip being about 60 degrees to the east. The vein, while clearly defined, swells and contracts in places, varying from five to fourteen feet wide and is well mineralized with copper pyrites, the ore averaging 3 per cent. copper. A second tunnel was driven at an elevation of 75 feet above the first and at that time was in on the vein 100 feet. Twenty feet higher still another tunnel was driven on the vein for 40 feet. No stoping had been done but the different levels were connected preparatory to stoping and the ore that was taken out was handled through the lower or main tunnel.

On the surface above the upper tunnel the vein was stripped and showed up strongly, crossing over a shoulder of the mountain. Two or three small diabase dykes were cross-cut in the tunnels and also show up on the surface. They cross the veins from wall to wall but do not run into the country rock. On a level with the upper tunnel, but some 550 feet to the north, is a small gulch. A cross-cut has been driven through the schist country rock to cut the vein. At this point the vein was found to be about three feet wide and not as heavily mineralized as in the main working. From the inner end of this cross-cut tunnel a drift was run to the north on the vein for 150 feet, while a drift to the south, towards the main workings, was run for 220 feet. In the south drift at 140 feet from the tunnel the vein has been replaced by a diabase dyke, but towards the inner end of the drift the vein comes in again with a width of eight feet, throughout which width it is well mineralized with copper pyrites. The vein has been traced for a considerable distance, both above and below the main

workings, and there is every promise of a large body of ore.

The Brown Alaska Company, whose headquarters were at Seattle, Wn., and who had a smelter at Hadley, Alaska, were the original operators. The plant installed by this company included an aerial tramway running 6,000 feet from a point just below the main tunnel to ore bunkers at Maple Bay, where loading facilities were provided. A 6-drill Rand compressor was installed at the beach and a pipe line laid to the mine.

The mining camp of Alice Arm, which is the tide-water outlet of numerous claims and prospects, as well as some properties already showing signs of being mines in embryo, most of which are scattered along or close to either Kitsault or the Illiance river, looks forward to rejuvenation next summer. The Esperanza is expected to continue shipping as well as development and is likely to be joined by the Lone Maid. Both are in the Kitsault section. The Horse Shoe and the Homestake, near the Kitsault Glacier, are to be further developed. As to operations on the Dolly Varden, little is known. The bunkers, railway, and mine plant, however, are deteriorating by reason of disuse and as many thousands of dollars are tied up in this equipment it is thought that action of some kind must be taken this year. The country back of Alice Arm is highly mineralized. It has long been a favorite stamping ground for the prospector and there is no doubt that it will see much activity this year.

Reports of progress on the property of the B. C. Silver Mines, Ltd., near the Premier Mine, Salmon River, continue to reach the Coast. It is said that the vein recently cut by a tunnel at a depth of 400 feet has proven to be 40 feet wide, with satisfactory gold and silver values. A drift now is being driven on the lead and the work is being continued over the full twenty-four hours every day. A large oil-driven compressor and a steel sharpener are being installed. This machinery, together with a large quantity of food and supplies, are being taken in over the snow.

**AINSWORTH.**—The Florence Mine, Ainsworth B. C., is likely to be taken over by a new syndicate. A group of Detroit bankers and manufacturers, headed by D. L. Robinson, propose to purchase the property, and to furnish up to \$600,000 for improvements and to increase production, if the present shareholders agree to the terms offered. A meeting of the latter will be held at the mine on April 4th to discuss the matter.

The syndicate will either take over the old company and increase the capital stock 1,750,000 preferred and 2,000,000 in common shares, or will organize a new company. It will receive 500,000 of preferred for the \$450,000 advanced for improvement. The sum of \$3.20 a ton on all ore mined will go into a sinking fund to retire the preferred stock. This does not include interest on the purchase, which must be paid separately. If there is no profit in the ore, interest must be met from other sources. Whatever profit accrues over \$3.20 a ton must be used for the further development of the mine or the call of the preferred stock at \$1.25 a share. The management remains with the present board and the stockholders until all the preferred stock is retired. The holders of present stock will receive an exchange for their stock share for share.

The \$450,000 referred to, it is explained, will be expended as follows: \$150,000 to retire present liabilities; \$175,000 for electric power plants; \$50,000 to enlarge mill to 350 tons; \$10,000 for additional mine equipment; and \$60,000 for mine development.

The consideration for the transfer of the property is \$1,250,000, to be paid from the production of the

mine, the basis of payment being \$1 a share and interest at 10 per cent if made from production, or \$1.25 and interest if the stock is called for before the production is completed.

E. R. Wolfe, president of the Company, makes the following statement:

"Production with the present equipment can pay for the mine in four years, but with the improved equipment, to be provided from the \$50,000, I believe it will be paid in three years. In the meantime the stock will draw interest at par, \$1 a share, beginning April 4. The \$3.20 per ton payments are based on ore to be mined, not milled. The net value of the mine ore is \$12 a ton. The consulting engineer for the purchasers, Frederick G. Lasier, who has operated mines in Colorado and Mexico, found 250,000 tons of ore in sight and 225,000 tons of probable ore. This is more than enough to pay for the preferred stock. Mr. Lasier's figures do not include extensions of known ore-shoots, which undoubtedly will be developed at great depths by advance of the Nos. 2 and 5 tunnels. These tunnels will attain depths of 1000 and 1350 feet, respectively, on the next known ore-shoot."

Ore receipts at the Trail Smelter, Consolidated Mining & Smelting Co., for the week ending March 14th totalled 8189 tons. There were two new shippers, the Galena Farm Mine, Silverton, and Fred. Bowden, of Chopaka in the Similkameen.

The shipments in detail follow:

| Mine                          | Tons |
|-------------------------------|------|
| Black Rock, Northport,        | 72   |
| Company Mines                 | 6923 |
| Fred Bowden, Chopaka          | 12   |
| Galena Farm, Silverton        | 29   |
| Henderson Gp. Smithers        | 27   |
| Knob Hill, Republic Wn.       | 159  |
| Krao, Ainsworth               | 18   |
| Lone Pine, Republic Wn.       | 108  |
| Paradise, Invermere           | 43   |
| Rosebery Surprise, New Denver | 141  |
| Silversmith, Sandon           | 383  |
| Standard, Silverton           | 145  |
| Surprise, Republic Wn.        | 104  |
| White Water, Retallack        | 35   |
|                               | 8189 |

## AN IRON AND STEEL PLANT FOR BRITISH COLUMBIA

### A Spokane Engineer Discusses the Problem

In discussing the general question of the supply of iron ore for this continent, "Iron Ore," Ispheming, Mich., in a recent issue quotes Chester T. Kennan, of Spokane, Wash., as follows:

There is a vast territory in northwestern United States and western British America which is now in great need of and could well support a large iron and steel plant. Such an iron and steel works could furnish its products to the Pacific coast, North and South America, and to Alaska and the Orient.

During the last two or three years there has been much agitation for the establishment in the northwest of a plant. The high cost of freight on manufactured iron and steel from eastern United States and from southern Colorado makes the cost of all kinds of iron and steel products unusually high in the northwest and all along the Pacific coast of both continents. In the northwest all the raw materials needed are found in abundance, and as the ore

is of excellent quality for iron and steel manufacture, it is believed to be only a question of time until larger works will be established.

Under the Pittsburgh basing point system, the cost to the western consumer of iron and steel shipped by rail is now the same whether purchased at Pittsburgh, Chicago, or Pueblo, Colo., and the rail tariff are the same from Pittsburgh to all the northwest. For illustration, the freight tariffs per gross ton from Pittsburgh to Helena, Mont., Spokane and Seattle, Wash., are as follows: Steel billets, \$33.60; structural shapes, \$26.88; bridge iron, \$33.60. steel rails, \$33.60, and drill steel, \$26.88.

Iron and steel works close to the Atlantic coast can ship their products via the Panama canal to Pacific ports considerably cheaper than by rail, but to points as far inland from the Pacific as Spokane and Helena there is not a great difference.

The average cost of transporting and handling Lake Superior ores from mine to Pittsburgh furnace is about \$3.25 per ton and it takes nearly two tons of such ore to make a ton of steel. The average cost of transporting and handling iron ore from mine to furnace in the northwest would not exceed \$1.25. Another advantage the northwest has is hydro-electric power that need not cost to exceed \$15 per horsepower per year, which would make rolling mill service remarkably cheap, and even admit of electric smelting of iron ores.

The iron ores of Lake Superior and the cokes of Pennsylvania are 1,500 to 2,000 miles apart. The Hartville, Wyo., iron ores and the Trinidad-El Moro coke used by the Colorado Fuel and Iron Co., are 500 miles apart. In the northwest, in no instance is the iron ore field further than 200 miles from the coking coal, and in some instances the iron ore is almost adjoining the coal or not more than 25 or 50 miles away.

Consumption of iron and steel products in the Pacific West has grown to the proportions of over \$400,000,000 per annum. The cost per annum for drill steel alone in the western mountains is over \$25,000,000. In view of these facts it is surprising that iron and steel manufacturing industries have not been established in the northwest. The lack of them is retarding the growth and prosperity of the country. It is hardly probable that the great iron and steel interests of the United States will allow British interests to monopolize the superior iron ores and coking coals of the northwest, and thereby gain an important advantage in the production of iron and steel, yet their present attitude appears indicative of that result.

For iron and steel making purposes the coking coals of Washington, Montana, British Columbia and Alberta are comparable with those of Pennsylvania and West Virginia and are far superior to those of Colorado. There are large iron ore districts in Washington, the Panhandle of Idaho, western Montana, and in British Columbia and quality compares favorably with those of Lake Superior.

The iron ores of Washington, north Idaho, and west half of Montana, are principally red hematite, while those of British Columbia are nearly all magnetite. Such magnetites as there are in Washington, Idaho, and Montana are usually located near the international boundary. Some of these magnetite deposits are very pure.

Preliminary figures by the Geological Survey showing the production of quicksilver in the United States in 1922, give a total of 6,497 flasks of 75 pounds net, as compared with 6,339 flasks in 1921, which was the smallest annual output in the 72 years of recorded production of domestic quicksilver. In 1922 California produced 3,494 flasks, Texas 2,725 flasks, and Nevada and Oregon 278 flasks.

## A SUBSTITUTE FOR DIAMONDS IN DRILLING

Volomite, a carbide of tungsten said to be made in Switzerland, is the hardest substance known, next to diamond. An article by Dr. Th. Reinhold, geologist to the Netherlands government, in the "Petroleum Times" of February 17th, describes its use and limitations in core drilling. It is set in a steel bit as are diamonds, but the pieces are larger and more of them are used. A thorough investigation into their use has led to the following conclusions:

The average cutting speed of a volomite bit is less than that of a diamond bit under the same circumstances.

The volomite bit cuts well in soft rocks such as shale or slate, sandy shale, soft sandstone, any porous limestone, and marl.

The volomite bit is especially useful in broken or shattered ground, which is especially dangerous for use with a diamond bit. If the volomite bit is broken or lost, the expense is not great. It is the best substitute for the diamond bit in such a case.

In soft ground where the use of a double-barrel core drill is necessary, the volomite bit can be used to advantage.

The conclusion in general is that volomite cannot replace the diamond for drilling, but that it is a useful adjunct, especially in dangerous, broken ground. The two bits can be used consecutively in the same hole.

**STOCK ISSUE WANTED** — In proven mining property, Shining Tree District; must have good directorate, assays, etc. and pay twenty per cent (including five per cent in stock) as commission. INVESTMENT SECURITIES SALES CO. 426 State Street, Schenectady, N.Y.

### PURCHASE OF GOLD ORES

The attention of prospectors and others is drawn to the provision in the Mining Act of Ontario authorizing the Department of Mines to purchase parcels of gold ore taken out by prospectors and others in developing or working mining claims. Arrangements have been made by which such parcels of gold ore, whether large or small, will be accepted by the Timiskaming Testing Laboratories at Cobalt, and paid for according to the schedule provided for the purpose. The Laboratories are operated under the auspices of the Department of Mines.

This offers a first class opportunity for testing the value of ores on a large scale, and also of turning ore of good quality into money for carrying on further development work. By special arrangements, on less than carload lots, freight rates on the T. & N. O. Railway are reduced 50 per cent.

The Laboratories are also equipped for working out the best methods of treatment for gold or silver ores of a refractory or unusual character.

Full information as to treatment charges, schedule of payments, etc., can be obtained from the undersigned, or from A. A. Cole, Manager, Timiskaming Testing Laboratories, Cobalt, Ontario.

THOS. W. GIBSON,  
Deputy Minister of Mines.

Toronto, 12th March, 1923.

## WIRE ROPE & FITTINGS

- Summary Report of the Mines Branch, 1920.  
The Mines Branch maintains the following laboratories in which investigations are made with a view to assisting in the development of the general mining industry of Canada.—
- Fuel Testing Laboratory.**—Testing value of Canadian fuels for steam raising and production of power gas; analyses, and other chemical and physical examinations of solid, liquid and gaseous fuels are also made.
- Ore-Dressing Laboratory.**—Testing of Canadian ores and minerals, to ascertain most economical methods of treatment.
- Chemical Laboratory.**—Analysing and assaying of all mineral substances and their manufactured products. Copies of schedules of fees, which are slightly in excess of those charged by private practitioners, may be had on application.
- Ceramic Laboratory.**—Equipment is such that complete physical tests on clays and shales of the Dominion can be made, to determine their value from an economic standpoint.
- Structural Materials Laboratory.**—Experimental work on sands, cements and limes is also undertaken.
- Applications for reports and particulars relative to having investigations made in the several laboratories should be addressed to The Director, Mines Branch, Department of Mines, Ottawa.
- Summary Report. The annual Summary Report of the Geological Survey is now printed in parts. Applicants should, therefore, state what particular geologist report is required, or what subject they are interested in.
- Memoir 108. The Mackenzie River Basin, by Charles Camsell and Wyatt Malcolm.

### For Economy Use Hercules Flotation Oil

The proof of the value of a flotation oil lies not in the cost per gallon, but in the amount of concentrate recovered by its use.

Pine Oil is the best frother known, and Hercules Pine Oils have the advantage of complying strictly with specifications and being uniform in every shipment.

We ask you to compare the price and value of Hercules Pine Oil with others on the basis of net cost per ton of ore treated.

We should welcome an opportunity to demonstrate to you the economy which results from the use of Hercules Steam-distilled Pine Oil.

LIMITED  
WELLAND ONTARIO

## Yes It's an "IRONCLAD"!

This Sullivan Longwall Ironclad is cutting up a 25-degree pitch in a 22-inch seam near Charleroi, Belgium. Production was doubled by the installation of this machine.

If you have difficult coal mining conditions, there's a Sullivan Coal Cutter which can solve them economically, for you.

Duluth, Spokane, Vancouver

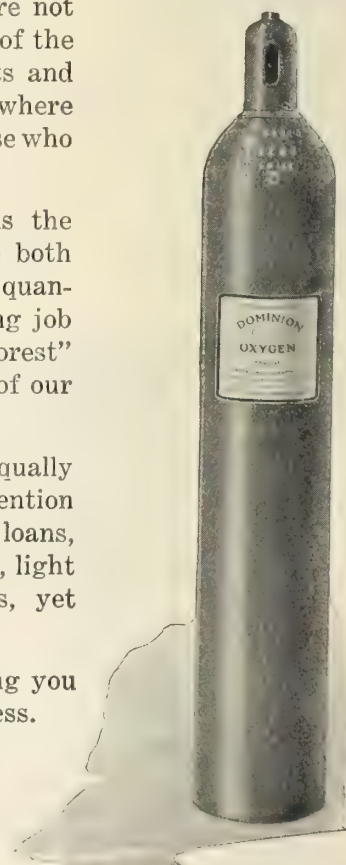

## We Are Your Neighbours

Unlike the man who made the better mouse trap and built his house deep in the forest where the world had to find a path to his door, we are not only making oxygen and dissolved acetylene of the highest quality, but have located our plants and warehouses in the busy commercial centers where our products are most easily available to those who need them.

An important part of Dominion Service is the promptness with which you can secure both oxygen and dissolved acetylene in unlimited quantities. Even though your plant or contracting job may be as inaccessible as the "house in the forest" we will find the shortest way to it from one of our ten plants and distributing warehouses.

Other features of Dominion Service are equally important to you—lowest prices, careful attention to shipping instructions, liberal cylinder loans, easily-handled cylinders of the newest types, light in weight to save transportation charges, yet ruggedly constructed.

We shall appreciate an opportunity of telling you how Dominion Service will help your business.

## DOMINION OXYGEN COMPANY, LIMITED

*Operating the Welding and Cutting Gas Division of  
PREST-O-LITE COMPANY OF CANADA, LIMITED*

**General Offices: 80 Adelaide St. East, TORONTO.**

**DISTRIBUTION POINTS:** Hamilton, Merritton, Montreal, Chawa, Quebec, Shawinigan Falls, Toronto, Welland, Windsor, Winnipeg.

# Cutting Coal Cutting Costs

## With the "Ingersoll-Rand Radialax"

When you can drive entries, take down roof, shear, cut out dirt and clay band, and undercut at any angle with one machine, as you can with the "Ingersoll-Rand Radialax," you can reduce production costs by using that machine.

Shearing and blasting on "open end" means more hard lump coal with less powder. The "Radialax" will cut out the band for a width of 12 ft. to a depth of 6 ft. with out moving the column set up. There is no other machine that does this so well.

*Begin to save money by asking for Bulletin K-400 describing the Radialax*

PROVINCE OF ONTARIO

DEPARTMENT OF MINES

HON H. MILLS, Minister of Mines

## Mineral Areas.

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favorable for the occurrence of minerals, 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver mines of Cobalt occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

## Economic Minerals.

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario:—actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluor-spar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, portland cement, brick and tile, meet every demand.

## Mineral Production.

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1921 to be worth \$48,128,387, of which the metallic production was \$27,574,202.

The following figures show the rapid growth of Ontario's mineral industry by five-year periods since 1891:

| Year.          | Value.      | Year.          | Value.       |
|----------------|-------------|----------------|--------------|
| 1891 . . . . . | \$4,705,672 | 1906 . . . . . | \$22,388,383 |
| 1896 . . . . . | 5,235,003   | 1911 . . . . . | 41,976,797   |
| 1901 . . . . . | 11,831,086  | 1916 . . . . . | 65,303,822   |

## Dividends.

Dividends and bonuses paid to the end of 1921 amounted to \$23,140,734 for gold mining companies, and \$84,388,185 for silver mining companies or a total of \$107,528,919.

## Mining Regulations.

A miner's license costs \$5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of \$2.50 or \$3.00 per acre, depending on location in unsurveyed or surveyed territory.

## Assay Office.

The Provincial Assay Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

## Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

## IMMIGRATION AND MINING

Who in Canada wants immigrants? From the recent public discussions in Parliament and in the press we gather that, though we all want immigrants on general principles, most of us object to an influx of new comers into our particular spheres of endeavour. The farmers of the thinly peopled West want no additional surplus to crops that remain unsold. Industrial workers in large numbers remain unemployed and their unions object to added competition for "jobs". The people of Quebec wish to settle their outlying lands with their own kith and kin, available in plenty from the natural increase in population and from repatriation. The railway and steamship companies, aided by the little band of altruists who wish to see Canada grow and prosper, alone uphold the cause of immigration. Our federal executive is strictly "on the fence."

The truth is that if we are to absorb large numbers of immigrants within a short period, it must be on the basis of a diversified and well-rounded development. This development must provide at one and the same time additional markets for the products of farm, mine, forest and sea, as well as for manufactured materials. We can depend upon the additional export of these products only to a comparatively limited extent. We must make our own markets within our own borders. Thus were the vast vacant spaces of the United States filled in a phenomenally short space of time, and only thus can we hope to effect a similarly rapid settlement in Canada.

Among the agencies that stimulated settlement in the central and western parts of the United States, none approached in importance the series of mining booms. These drew men, a fine type of men, from all quarters of the globe. Once there, a large part of them settled on the land, where they found ready and lucrative markets in the growing mining camps. General industrial development followed settlement. The chief legacy of the mining booms of half a century is the rapid settlement and the present prosperity of the quarter-continent throughout which the booms took place.

What happened in the United States will take place in Canada, probably not on the same grand scale, but with the same general effect. The fertile valleys of British Columbia will be tilled when near-by mines and smelters provide a market for their produce. The prairie lands will smile in full prosperity only when

the discovery of iron ore within reach of Alberta's coal beds shall have stimulated there the growth of a second Pittsburgh. Winnipeg's future as a great industrial centre will be realized only when the mines of its hinterland send down their products to this gateway of the West in exchange for the food and supplies they require. When Canada commences to use Canadian iron ore, northwestern Ontario will hum with activity.

The nickel mines of Sudbury have stimulated already the settlement of farming districts that would still be unproductive but for their operation. The gold district of northeastern Ontario has proved its potency as an agency for settlement, and the new area in northwestern Quebec promises to do likewise on behalf of this eastern end of the Great Clay Belt.

Recently Parliament spent days in futile argument about the assistance of immigration to the extent of \$700,000. During the progress of the debate, the sum of \$700,000 was voted, with little protest, to provide the salaries of outside immigration officials. The days and weeks of speechifying, where they meant anything, discussed the principles upon which an immigration policy should be based. Nowhere in the debates or in the public discussion that followed have we found evidence that it is clearly understood what a great part mining development can, and must, take in settlement.

If Canada is to be settled rapidly, it will be principally by virtue of her expanding mineral industry. When this fact shall have been grasped clearly by a sufficiently large part of the Canadian public, then, and only then, can we expect our business men, our industrial leaders and our legislators to take steps to encourage and aid this, the most effective of all immigration agents.

## A GIFT TO SCIENCE

In his letter offering to the Royal Society a gift of £100,000 for the purposes of scientific research, Sir Alfred Yarrow has given a remarkably clear and concise statement of the circumstances and importance of this branch of science, now and forever dependent principally upon such private benefactions, in addition to public subsidy. We reproduce this letter in part on another page.

Fortunately for the industrial future of Britain, there are a number of her leading citizens, in both private and public life, who are firmly seized of the prime importance of scientific research. Under the

stimulus and direction of a well organized and vigorous National Research Council, literally thousands of commercial firms have combined, each with his fellow, in research associations. This latest benefaction will, we take it, be applied to the development of pure science rather than to its industrial application.

In Canada we have had as yet neither public subsidy nor private gifts to research on a scale that ensures the future of our industry and commerce. With the exception of work in our universities and in certain government departments, research in Canada is conspicuous principally for its absence. There are some notable exceptions to this rule; but as yet the bulk of our industries remain untouched by the magic wand of the researcher.

### MR. BELLEW AND LABRADOR GOLD

At last we have a signed statement from Mr. Henry C. Bellew, M.E., the promoter of Labrador Gold, Limited. It appears on page 581 of the March 15th issue of "The Canadian Gazette," a semi-official publication issued in London. We must confess to being rather disappointed with the brevity and vagueness of the information about the gold described under the caption "The Gold Strike on the Labrador." In three-quarters of a page Mr. Bellew mentions gold three times. The remainder is a very good description of that part of the Labrador coast, which Mr. Bellew knows well from his unsuccessful search for pulp-wood there.

"That it was known for many years that gold was said to exist on the Labrador is a well-established fact." With this remarkable statement Mr. Bellew introduces the story of the early explorers on "the Labrador". Coming down to the more recent interest he says:

"In view of the interest lately taken in Labrador owing to the reported gold discoveries upon Big Brook and Black Duck Brook, a few words about these 'rivers' may not be amiss."

Then follows the excellent description of the coast line above referred to. At the end, getting right down to the point announced in the title of the article, Mr. Bellew says:

"Gold was first discovered in Big Brook in July, 1921, and during the month of September, 1922, in Black Duck Brook. The rivers flowing into Adlavik Bay were reported also to be rich in gold during November, 1922, resulting in quite a stampede for mining licences for these rivers, all of which points to an old-fashioned rush as soon as navigation will permit this summer."

If only Mr. Bellew had been freer with his information and less non-committal in his statements in this article of his, we might have had more comment to make. Possibly the strict laws in Britain dealing with fraud have something to do with Mr. Bellew's guarded

statement. We have gathered from Canadian publications a wealth of information about the placer fields about which Mr. Bellew is in this case so reticent; but of course, that had been merely passed on to the reporters, and thus circulated not only free of charge, but free of any possible embarrassing consequences to Mr. Bellew.

On to Labrador and fortune!

### MR. CAMPBELL REPLIES

After a winter vacation that has re-invigorated both mind and body, Mr. C. M. Campbell has returned to his professional duties at Cassidy, Vancouver Island. Likewise he has returned promptly to the defence of a principle that he considers rightly to be of grave importance. Though we do not agree fully with Mr. Campbell in his deductions and conclusions, we respect and admire the spirit that prompts him to uphold, single handed, the cause of conservative judgment and regulated statement as applied to Canada's mineral resources.

There is no doubt that part of the statements and deductions to which Mr. Campbell takes exception are exaggerated in much the way he suggests. Startling statements usually contain an element of exaggeration; but they may be eminently useful in spite of this fault, provided the cause is just and subsequent action well-founded. There is no doubt that the general public has been insufficiently informed about the facts of the mining industry and its potentialities. These have now been well advertised by the addresses of Dr. Corless and others. The limitations of our own and any mining industry must not be overlooked, and Mr. Campbell has attended to that phase of the subject. We judge, however, that the case for sound and economical development of our mineral resources can be left safely in the hands of our trained mining engineers.

A point that has not been discussed at the length it deserves in the series of letters and addresses (not neglecting the verses) centering round this question, is the influence the mining industry exerts, directly and indirectly, in the development of the other industries, basic and secondary, in a new country. This influence, we would judge, has a value far in excess of that marked by the actual mineral production. We have indicated today in another place the intimate relation of mining development and settlement of the land. This applies similarly to all other industries, as well as to the professions.

It may be that the mining industry is to a new country what leaven is to the loaf. History justifies this conclusion. We would judge that those who have argued optimistically about the future of our mining industry must have this point in mind, though they have not always expressed it. We would judge that Mr. Campbell, on the contrary, has confined himself

to the letter of the argument, else he would have credited mining with a larger importance in our national development.

An important point that, though not new, has not been touched upon heretofore in this controversy, is brought out clearly by Mr. Campbell in today's letter. He points out that in our zeal for greater and still greater mineral production, we are apt to overlook the basic requirements of conservation and to squander, for a temporary gain, an unreplaceable and rare resource. This is well illustrated by two remarks that have been going the rounds recently. An English writer says: "Always remarkable for improvident destruction of natural wealth, the Americans have destroyed their national wealth with a recklessness that strikes many shrewd observers as suicidal." J. Parke Channing said recently: "I think we can safely say that the copper resources of the world are extremely limited, — more limited than any other of the base metals; and unless new deposits are found, we will be threatened in fifteen years with another shortage of copper." We commend this point in Mr. Campbell's letter to the attention of every thoughtful mining engineer.

### ARGONAUT FINANCING

In the letter we print today, Mr. J. H. Rainville, president of Argonaut Gold, Limited, has chose to confine himself principally to recrimination. We had hoped he would state publicly the grounds upon which the recently authorized addition of \$1,000,000 stock was made and upon which his own high hopes and those of Argonaut shareholders have been based. It is interesting to know that Argonaut has acquired control of the Huronia Company as well as additional claims adjoining the Argonaut and others in Rouyn township; but it would be much more to the point to know the basis for that extra million of stock. Rumours have been in circulation lately as to new developments, and we had hoped for confirmation of these rumours from Mr. Rainville. He does not choose to discuss the matter, so we must perforce stick to the facts upon which we based our former judgment of the case.

Mr. Rainville's personal probity is beyond question, as is his faith in the Argonaut property and his determination to make it succeed. He has staked both his personal fortunes and his reputation upon the success of the property. We fear, however, that his enthusiasm has led him to adopt financial methods that are not in accord with sound mining practice. His judgment in mining matters can be called in doubt with reason, judging from another and much less reputable venture with which he has associated himself.

While the Argonaut property was still virtually a prospect, its promoters financed it by public subscrip-

tion, the method adopted involving a ruinous discount on the sums subscribed and a corresponding burden on the property. A year ago when the mine records showed a very modest amount of ore disclosed in the workings, a series of advertisements over the company's name soliciting subscriptions to stock described "ground only scratched and \$4,000,000 of gold already located" in "the most persistent, most permanent and most wonderful vein ever opened up in the North Country." This latter is quoted from Mr. J. W. Morrison, then and now in charge of mining operations, who, in view of the fact that at the time he was searching vainly for the continuation of the faulted vein, might well have denied or qualified publicly the ridiculous statement attributed to him.

Mr. Hardman's letter, which we published last week, deals principally with this period of the property's development. It is noticeable that, in upholding the mine's value, he discreetly omits mention of the *quantity* of ore available — rather a serious omission, in view of his being an engineer. We should like to point out for Mr. Hardman's benefit, by the way, that we (the editor) are solely responsible for the statements he criticises. We are surprised to learn (by the way, also) that Mr. Hardman considers himself the reverse of an optimist; we had always understood that he and his undertakings were at the hopeful end of the scale.

We have been informed privately that the mining position of Argonaut is now vastly improved over that of a year ago. We hope that the rosy views of today may prove to have a more substantial foundation than those expressed a year ago. We have been informed too, that the milling difficulties are all overcome, only to learn later that the method to be adopted is still in doubt. We should like nothing better than to see a substantial new unit added to our gold mining industry by the shores of Beaver-house Lake. But the most fortunate outcome will not excuse the financial methods that have been adopted to raise money for the development of Argonaut, which methods we hold to be intrinsically unsound.

Shortly after the Hollinger became a mine, one of its original owners explained to a young engineer seeking advice that he and his partners never had offered, and never would offer, to the public any mining stock on which they could not ensure a reasonable return. This stand exemplifies what is, or should be, axiomatic among mining men. If the rule is broken, it may or may not be at the expense of those that buy the stock; but always it is at the expense of the mining industry as a whole, whether the mine pays or not. The "Canadian Mining Journal" holds a brief for the mining industry. We find that the Argonaut promoters have broken sadly the rule, and we have pointed to the fact publicly. They may retrieve themselves; we hope they will; but a successful issue should not be allowed to conceal the facts of a false start.

## THE NORTHERN PROSPECTOR

With Summer gone, and Autumn chill  
Painting its colors on the hill,  
My meagre store of treasure spent,  
I fill my packsack, and content  
Stem with my bark the current through  
With aspirations born anew.

When Winter's skies are gray and cold  
I still pursue the hunt for gold.  
My snowshoe's trail invades the lair  
Of wolf, and moose, and slumb'ring bear.  
My hut in banksian thicket's lee  
From howling blizzard shelters me.

When Springtime's mist on marshland lies,  
My tent's invaded thick with flies;  
Clouds of mosquitos buzz and sting;  
The sandfly comes on noiseless wing;  
And in the alders' moistened shade  
The blackflies lay an ambuscade.

Tormented by the pests, I swear  
I'll leave this land for anywhere;  
And find in some enchanted clime  
A peaceful life. Then comes a time  
When Summer sun with drying ray,  
Subdues and drives the pests away.

The land's wide treasures still unfold,  
From where are ridges veined in gold,  
To other rocks, with silver seams,  
Rich as the treasures seen in dreams.  
The landscape fair with sunlight kissed,  
Makes every man an optimist.

Away! dull thought of Winter skies;  
Away! remembrances of flies;  
With life and health the chance is there  
To wrest from nature treasures rare;  
To carve in stone the lasting fame  
That gives to some great ledge, my name.

Henry Elwood McKee.

## A GIFT TO RESEARCH

Sir Alfred Yarrow, the famous designer and builder of high speed vessels such as torpedo-boat destroyers and other special craft, recently gave £100,000 to the Royal Society, London, for the purposes of scientific research. In his letter offering this gift in the service of research, Sir Alfred says:

"I have, for many years, held the view that the prosperity of this country has been greatly hampered in the past for the want of better promotion to scientific investigation and its application to practical affairs. I am convinced that the future prosperity of this country will be largely dependent upon the encouragement of original scientific research.

"The birth of new industries, and the development of existing ones, are due largely to the growth of science, thus securing employment and the welfare of the whole community being advanced. It is doubtful whether even yet it has been realized how completely this country would have been at the mercy of our antagonists in the late war had it not been for the research work done by our scientific men before the war and during its course.

"I desire to mark my sense of the value of research to the community by offering, as a gift to the Royal Society, £100,000, to be used as capital or income for the purposes of the Society, as the Council may think fit, because I recognize that conditions alter so materially from time to time that, in order to secure the greatest possible benefit from such a fund, it must be administered with unfettered discretion by the best people from time to time available. Care must, of course, be taken that a gift from the fund shall in no case lessen any Government grant.

"In accordance with your practice, you would, I assume, appoint a committee to administer the fund, and would also frame rules for the guidance of the committee, while reserving the right to alter such rules from time to time; and I would suggest that they be reconsidered by the Council every tenth year so as to meet modern needs. I should prefer that the money be used to aid scientific workers by adequate payment, and by the supply of apparatus or other facilities, rather than to erect costly buildings, because large sums of money are sometimes spent on buildings without adequate endowment, and the investigators are embarrassed by financial anxieties. Although I thus give a general expression of my wishes, I do not intend, by so doing, to create any trust or legal obligation for their fulfilment.

"In conclusion, I should like to record my firm conviction that a patriotic citizen cannot give money, or leave it at his death, to better advantage than towards the development of science, upon which the industrial success of the country so largely depends."

This letter shows a grasp of both the uses and the needs of scientific research that all too few, either in Britain or in Canada, possess at present. Sir Alfred Yarrow's own business has been founded upon the systematic application of that spirit of well-directed scientific curiosity that we call research, as are most of the great and sound business enterprises that have made Britain famous as the world's workshop. With his intimate knowledge of conditions in Britain, Sir Alfred discerns a slackening-off of the effort upon which her commercial supremacy rests to such a marked extent; hence his magnificent gift in aid of that branch of scientific endeavour by aid of which he accumulated his personal fortune.

A discerning note of direction contained in this letter is the advice that the gift should be used to support the personal needs of researchers rather than to provide them with the premises for their work. This is in marked distinction to the common tendency, which requires a visible monument in the shape of buildings or mechanisms to provide a memorial to the donor. This added and unusually discriminating touch may well be marked for reference by all interested in the fortunes of scientific research.

A sixty-ton shipment of pitchblende received lately in Belgium from the new deposits in the Katanga region of the Belgian Congo contained 50 percent uranium oxide, from which about eight grams of radium could be extracted. It is this phenomenal richness of the new deposits that has given them their present control of the world market.

## RECALLING THE ALCHEMIST

By P. B. McDONALD\*

What chemist, toiling in his laboratory and making those musty smells typical of the profession, has not been inspired by visions of the medieval alchemists? These same alchemists, some authorities say, were stupid obstacles in the path of knowledge; whereas other authorities glorify them as the wise men of their time, working in an age of darkness for the fragments of knowledge that have grown into modern chemistry. At any event, the medieval alchemist was a picturesque figure; visions of him bending in his robes and cap over his curious mixtures have lent the color of romance to many a dreary laboratory, where testing of fertilizers and analysis of slags have replaced the search for the philosopher's stone and the elixir of youth.

Alchemy has been distinguished from chemistry by Perpetys as being the art of trying to complete in the laboratory the process that nature began; while chemistry is the art of destroying the compounds nature has formed. That is, the alchemists wished to change base metals into gold and silver, prolong life, raise the dead, create human beings by chemical formulae, and generally to learn the basic and mystic secrets of matter. They were influenced by religion and sex, since those mysteries were of paramount importance. One prevalent belief was that unity is a trinity, and trinity a unity; that the material world is composed of sulphur, mercury, and salt, just as the divine world is composed of Father, Son, and Holy Ghost. Mercury, said these learned men, is the passive and female principle corresponding to matter; sulphur, the active and male principle, is force; salt the middle term, is movement which applies force to matter.

These principles were harmonized with the teachings of Aristotle, whom they blindly followed. The great Greek scientist had suggested that all things consisted of four elemental properties; fire, the property of dryness and heat; air, the property of wetness and heat; water, the property of wetness and cold; and earth, the property of dryness and cold. The alchemists adopted these four states of matter and sought them in all substances. Everything hot was called fire, everything cold and subtle was called air, everything moist and fluid was called water, and everything dry and solid was called earth. Quoting from J. Cambell Brown's history of chemistry, "But as heat changed liquids to vapor, and consumed solids, they reduced the number of visible elements to two—earth and water, which contained within themselves the invisible elements fire and air. They were thus able to apply the conception of the three principles to that of the four elements. Earth corresponded to philosophical sulphur, and water to philosophical mercury. Later when they conceived philosophical salt, they devised a fifth element called quintessence, or ether, which corresponded to the third principle." This was in agreement with Aristotle because he had recognized a fifth element of ether and added it to the standard four. If an alchemist distilled wood and obtained an inflammable gas, a liquid oil, and a solid residue, he said that he had decomposed the wood into its elements—fire, water, and earth.

The metals, they thought, were conceived by sulphur acting as father and mercury acting as mother. These were not ordinary sulphur and mercury, but philosophical

principles of them. Nature sought to produce perfect metals of gold or silver, but was checked by such causes as impure mercury or sulphur, lack of time in the bowels of the earth, planetary influences, etc. Instead then of gold and silver, were produced the imperfect metals of mercury, copper, iron, tin, or lead. As to planetary influences, it was said that the influence of the sun brought gold, of the moon silver, of the planet Mercury mercury, of the planet Venus, copper, of the planet Mars, iron, of the planet Jupiter, tin, and of the planet Saturn, lead. Paracelsus, who was born the year after the discovery of America, declared that he could calculate when and how this planetary influence took effect. This belief in the relation of the metals and the planets had come down the ages from the Babylonians.

In his famous play "The Alchemist," produced in 1610, Ben Johnson has the alchemist Subtle defend his art to a doubter named Surly. Following is part of the conversation in the second act:

Seems so impossible?"

*Subtle.* "Why, what have you observed, sir, in our art,

*Surly.* "But, your whole work, no more.

That you should hatch gold in a furnace, sir,

As they do eggs in Egypt!"

*Subtle.* "Sir, do you

Believe that eggs are hatched so?"

*Surly.* "If I should?"

*Subtle.* "Why, I think that the greater miracle.

No egg but differs from a chicken more

Than metals from themselves."

*Surly.* "That cannot be.

The egg's ordained by nature to that end,

And is a chicken *in potentia*."

*Subtle.* "The same we say of lead and other metals,

Which would be gold if they had time."

*Sir Epicure Mammon.* "And that

Our art doth further."

*Subtle.* "Aye, for 'twere absurd

To think that Nature in the earth bred gold

Perfect in the instant; something went before.

There must be remote matter."

A little later Subtle launches into a detailed explanation, which must have been somewhat tiresome to the audience, if audiences in Shakespeare's day were at all like those of our modern business-men. During his speech Subtle refers to sulphur and quick silver as "the parents of all other metals."

"Nature doth first beget the imperfect, then  
Proceeds she to the perfect. Of that airy  
And oily water, mercury is engendered;  
Sulphur of the fat and earthy part; the one,  
Which is the last, supplying the place of male,  
The other of the female in all metals.  
Some do believe hermaphrodeity,  
That both do act and suffer."

It is difficult for us to realize the extent and ramifications of medieval alchemy. For centuries these quacks and wise men (for they were a little of both) developed their systems and influenced the life of their time. All kinds of magic and mumery became added to their practices, making gunpowder to compounding love philtres. But many of the alchemists were monks, and worked with a

\* College of Engineering, New York University

...s purpose rather than to make money. They would communicate their knowledge, but preferred to restrict it to a select circle. Brown gives a medieval recipe for rendering the human body immune to fire: "Take juice of double yulya, white of egg, seeds of persil, and lime. Pound together, and prepare them with white of egg mixed with juice of sapin. Anoint your body or hand with this composition, allow it to dry, repeat the anointing, and then you can bodily sustain the ordeal by fire."

Almost invariably they disregarded gases. When they wished to heat anything for a long period at a uniform temperature, they made use of a special furnace. With this they often used a glass vessel hermetically sealed, which they called the 'philosopher's egg.' As there was no escape for vapor or heated air, this piece of apparatus became a sort of bomb-shell, and not infrequently exploded with disastrous results to the alchemist.

In addition to the seven metals mentioned, they used antimony sulphide and bismuth. Zinc was held of small account except in the making of alloys, and was not recognized as a distinct metal until the sixteenth century. Compounds of potassium and sodium were known; sodium carbonate, for instance, came from the Lakes of Natron in Egypt, where it had been obtained for centuries for preserving mummies. Ammonia was known, particularly as sal ammoniac, but of ammoniacal gases, as of all gases, they were strangely ignorant. Says Brown, "Paracelsus mentions the production of an inflammable gas when iron is treated with acid in water, so he must have at least seen the flame of hydrogen; but he went no further, and it was left to Cavendish in 1766 to discover this important element. Sulphuretted hydrogen was observed as an unpleasant odor arising in certain chemical operations, but the gas was not known."

Of the alchemists in general, H. G. Wells says in his "Outline of History," "These alchemists were in close touch with the glass and metal workers and with the herbalists and medicine-makers of the times; they pried into many secrets of nature but they were obsessed by 'practical' ideas: they sought not knowledge, but power; they wanted to find out how to manufacture gold from cheaper materials, how to make men immortal by the elixir of life, and such vulgar dreams. Incidentally in their researches they learnt much about poisons, dyes, metallurgy, and the like; they discovered various refractory substances, and worked their way towards clear glass and so to lenses and optical instruments; but as scientific men tell us continually, and as 'practical' men still refuse to learn, it is only when knowledge is sought for her own sake that she gives rich and unexpected gifts in any abundance to her servants. We live today largely in the age of the alchemists, for all our sneers at their memory. The 'business-men' of today still think of research as a sort of alchemy."

### AN ENGLISH OPINION OF CANADIAN GOLD AREAS

A general study of the gold mining possibilities of northern Ontario and Quebec is given in the "Mining Magazine" (London) for March by A. L. Webb in an article, "The Future of Central Canada as a Gold Producer." Mr. Webb sums up his impressions thus: "The conclusion is that, while proof of mineral value is abundant, only indications, and not definite discoveries, will be the rule in the first stages of development of Central Canada. The diamond-drill is more and more becoming the means of locating ore-bodies, and values are being tested by winz- ing and underground development. These undertakings

are beyond the scope of individual enterprise. More capital is required than the prospector is prepared, or able, to find and failure is quite as likely as success to attend his efforts. Success will, however, more than counterbalance a number of failures, and this principle is behind the numerous enterprises which are today being financed in the United States for thoroughly and scientifically testing each individual deposit."

### SMILES

A remarkable statement by Capt. P. Louis Bowler, from which the following paragraphs are extracted appeared in the March 17th issue of "The Mining World and Engineering Record." Evidently the editor of this mining publication, as well as Capt. Bowler, lapsed a trifle on Canadian geography, or else both studied a very small-scale map, without any scales of miles, with this result:

"The opinion of well-informed mining men is that the year 1923 is destined to witness a gold rush to Northern Ontario, Quebec Province and Labrador, by reason of the recent discoveries, and information regarding the great extent of the rich gold-bearing belts reaching from Timmins, Porcupine, Kirkland and Larder Lakes in the west to "Stagg Bay," "Big Brook River" and Hamilton inlet on the Labrador coastline, as its eastern point, embracing a gold belt approximately 350 miles in length, and about 200 miles in breadth. So far as ascertained within this area, there are two defined series of reefs, running parallel with each other, and recent discoveries have disclosed wonderfully rich and extensive deposits of gold-bearing gravels lying adjacent to long stretches of outcrop lodes showing remarkable values in its veins and fractures.

"In my last article on gold in Ontario, which you published, I hinted that great discoveries would be made east and N. E. of Kirkland and Cochrane. The news now to hand has borne out my statements. A great rush is taking place to Stagg Bay and Big Brook river, where many washings from 25 to 56 lb. of gravel have yielded to the lucky panners \$100.00 worth of gold, while in several creeks gold dust lies on the surface, and at 5 ft. depth large placer nuggets have been secured.

"Another great rush is developing at Rouyn, 50 miles east of Dane Station on the T. and N. O. Railway, laying between Opasatika Lake and Kinojevis Lake, all east of Kirkland and Larder Lakes. Prospectors have found in this field veins yielding up to \$1,000 per ton; also astonishing yields from alluvial ground. Some of the outcrops are very wide, and give every appearance of being deep-seated.

"Thousands of hardy prospectors are awaiting the snow to melt to go in, and old-timers who have pegged out claims exhibit almost childish enthusiasm on the extraordinary results of their sampling; while geologists and mining engineers are all agreed that there lies in these belts an enormous source of untapped wealth, between Porcupine and the Labrador Coast."

Now that Capt. Bowler has corroborated in London the statements about Labrador Gold made so frequently in Canadian newspaper advertisements, who can doubt them? The alluvial ground in northwestern Quebec (which we in Canada learn of here for the first time) is evidently a small surplus brought by the glaciers from Labrador during one of their periods of promiscuous rambling across the continent. When Capt. Bowler starts on his tour of inspection of the new gold field across-country from Porcupine to Hamilton Inlet next summer, it would be advisable for him to take an extra pair of socks and some extra grub in addition to his usual equipment for woods travel.

## Use of Welding at Mines And Metallurgical Works\*

The use of oxy-acetylene at coal mines is almost universal, and to-day the process is being extensively employed also in the yards and at the docks of the distributor.

Coal handling machinery for unloading colliers and coal barges and for loading railway cars and trucks is composed for the most part of heavy units. This machinery is usually operated to capacity when shipments are being received or dispatched and when a breakdown occurs it is always urgent to effect repairs

Fig. 1. Parts Reclaimed by Welding

with the least possible delay, not only to avoid demurrage charges but to make way for other shipments. In such emergencies oxy-acetylene plays a very important role.

The superintendent of the central welding and repair shop of a large coal company in the Great Lakes district states that he always depends on oxy-acetylene for the repair of parts that are urgently needed. This company owns several coal yards, conducts an interstate business, and operates approximately four miles of docks. Oxy-acetylene welding and cutting apparatus is used in yards and at the docks for repair and reclamation work, a large part of which is done

Fig. 3. Wrecked Cast Steel Cable Sheave Wheel After Reclamation

in a central shop. There is considerable work, however, which can be done in place and which it would be difficult to bring to the shop, and portable equipment is kept in readiness for emergency work of this kind.

The four small wheels shown in Fig. 1 are cable

\* By courtesy of "Oxy-Acetylene Tips."

carriers. When received from the mill these were  $\frac{3}{4}$  in. too narrow. They were sent to the welding shop where a strip of steel  $\frac{3}{4}$  in. wide was welded to the inside of the wheel rim to bring it to the proper width. Three of these wheels in the photograph show the welded surfaces before machining. The remaining one shows the job after machining. The work was done in less time and at less cost than would have been entailed in providing new wheels. When the rims or flanges of wheels of this kind are badly worn in ser-

Fig. 2. Other Typical Reclamation Work

vice, it is customary to reclaim them merely by building up the worn surfaces with the welding blowpipe and a suitable filler rod.

In the same picture are seen a gear wheel and a boom drum part, both of which were reclaimed by welding. The part contains approximately 40 inches of welding, including the building up of the shaft which is clearly seen in the picture.

Fig. 2 shows a number of objects that had been reclaimed by welding. At the right is an air compres-

Fig. 4. Miscellaneous Machinery Parts Reconditioned or Repaired by the Oxy-Acetylene Process

sor cylinder. To make this cylinder adaptable to the machine for which it was intended it was necessary to increase the width of the flange (shown in the fore part of the picture) by  $1\frac{1}{8}$  in. To do this a casting like the one shown leaning against the reclaimed cylinder was made and welded onto the flange in place.

Fig. 6. Fire Destroying a large Concentrating Plant

Fig. 7. Cutting a lane through the Tangled Mass of Steel

Fig. 8. The Wreck of the Concentrator, showing Removal of Steel Debris after being cut by Oxy-Acetylene Torches

ally cast, thus providing the additional  $\frac{1}{8}$  in. necessary for the gasket. The compressor unit is valued at several hundred dollars and but for oxy-acetylene it would have been a complete loss excepting for its scrap value. The other objects in this picture are a gear wheel, a derrick part and an eccentric shaft with wrist pins in the foreground. All of these were saved from the scrap pile by oxy-acetylene.

The cable sheave wheel in Fig. 3 had two broken spokes and the hub was badly worn. The wheel is cast steel. The broken spokes were welded and the hub was built up 2 in. on each side. This work was done in less than a half a day and saved the cost of a new wheel, which in this instance would have been considerable because of the fact that the particular size and type of wheel is obsolete and a special casting

would have been necessary. Fig. 5 shows an oxy-acetylene operator welding copper bonds on crane rails of loading and unloading tipples. The welder is really rebonding in this case. After the bonds have been in service for several months they become more or less oxidized and the constant vibration tends to crystallize the metal which eventually breaks. The breaks invariably occur where the wires are bent. There is no instance in which one has broken at the weld. This company makes all of its bonds in yards and at the docks with wire reclaimed from old motors and welded by the oxy-acetylene process. In rebonding the old weld is melted down to form a surface for the new bond and the connection is then made with the blow-pipe, using a piece of the same kind of wire for filler rod. The same filling material is used when the bonds are made on new rails. The time required to replace a broken bond with a new one is approximately four minutes, including the preparation for bonding and moving the equipment from one rail joint to another. It will be noted that the bonds are welded to the flanges of the rails. It is not practicable to weld either to the ball or the web because of the double flanges on the wheels of the cranes.

Other oxy-acetylene work accomplished by this company and which is considered as ordinary practice includes repairs on various parts of clam-shell buckets.

Fig. 5. Oxy-Acetylene Operator Welding Copper Bonds to Crane Rails

Worn edges are built up. If one of the large arms on the side of the buckets breaks, and breaks are not uncommon, instead of buying an entire new arm only the angular section of the arm where it is attached to the side of the bucket is purchased. This is a special casting. The straight section of the broken arm is then cut with oxy-acetylene and welded to the new casting. This operation saves approximately \$200 each time a repair of the kind is made. Cable fair-leadings on clam-shell buckets when worn or broken are welded and machined, being thus reclaimed at a fraction of the replacement cost.

In maintaining the steel structures of the coal handling machinery, oxy-acetylene welding and cutting are often used. These structures are mobile and the stresses to which they are subjected are constantly at work loosening joints and not infrequently breaking members. Repairs on these parts can usually be effected without dismantling them. The operator takes his portable apparatus to the points where the work is to be done and does all the necessary welding and cutting in place.

The company operates a large fleet of motor trucks and one welding operator spends at least a day each

week in the garage making repairs. The trucks have all-metal, automatic dump-bodies. Welding and cutting work in the garage consists of building up worn parts of the body-lifting devices and repair of frames that are broken or the strengthening of the weak joints by reinforcing them with welded patches. There is also considerable cast iron and aluminum welding on crank cases, burning out of carbon with oxygen and general maintenance work.

Figures 6, 7 and 8 illustrate a fire that destroyed a large concentrating plant in a Western mining camp a few months ago. These pictures show the big fire in progress, the devastation that was wrought and oxy-acetylene cutters engaged in clearing away the debris. Incidentally there goes with these photographs a chapter of emergency service that is worth reviewing.

No sooner had the smoke cleared away above the ruins of the burned concentrating plant than the management took steps to remove the wreckage which covered acres of ground, a veritable morass of warped steel. It was important to make way for the construction of the new mill with the least possible delay, because the large mines and the smelter would have to practically close down until the new concentrating mill was completed and in operation.

An emergency call for oxygen was one of the preparatory steps. Then an order for four generators, eighteen cutting torches and various other equipment was placed with a large apparatus manufacturer, and within two weeks a crew of fifteen oxy-acetylene cutters was at work burning a lane through the wreckage. The operation was somewhat similar to cutting a road through heavy timber with a crew of lumberjacks.

As soon as a passage was opened, space was cleared at the further end and construction of the new mill was begun, the operators meanwhile clearing away the remaining wreckage as construction progressed, so the erecting crews might encounter no delay.

The mechanical superintendent was greatly pleased with the service rendered by the apparatus company. At last reports practically all of the cutting had been completed, and it was said that many applications of the oxy-acetylene process would be made use of in the construction of the mill. Even at that time the company was constructing a 12-in. water pipe line of steel, all the joints of which, including longitudinal, were being welded.

## NEW VANADIUM DEPOSIT

There is reported in the "Engineering and Mining Journal Press" of March 24th a new deposit of vanadium ore in Garfield County, Colorado, that promises to re-establish the production of vanadium on this continent, which was discontinued shortly after the Vanadium Corporation of America had effected a monopoly of the chief known supplies on this hemisphere. It is estimated that during the current year there will be produced from the new deposit 10,000 tons of ore containing 400 tons of vanadic acid. ( $V_2O_5$ ).

Brazil produces about \$3,000,000 annually in gold, most of it from mines of the St. John del Rey Mining Company, a British company.

Recent discoveries have brought Venezuela to the fore as an oil producer.

# CANADA'S MINERAL RESOURCES

MR. C. M. CAMPBELL, AGAIN URGES CAUTION  
IN ESTIMATES AND FORECASTS

To the Editor,

Canadian Mining Journal

Sir:

I have just returned to Canada after several months' absence. I had hoped when I left that this discussion was ended, but on looking over the back numbers of the "Journal" I find that it has been a live issue. Even at this late date it appears that another letter is in order.

Mr. Mickle's letter, in particular, has been featured both in this Journal and in the "Bulletin." Your editorial comment is that I have "undoubtedly fallen into a pit." Dr. Corless endorses it and "J. C. M." adjures me to answer it.

Mr. Mickle's claim is that the "positive" rule that governs the estimation of ore in a mine does not apply to areas like Cobalt and is "entirely illogical" when dealing with national mineral resources. "It is a fact," he says, "that by a collection of risks, risk can be eliminated," and he uses a raffle as an illustration. He states that if you buy all the tickets in a raffle you eliminate risk for you are sure to get the prize. That is true; but if you buy all the prospects in a mining district you do not necessarily buy even one solitary mine and you do not, therefore, eliminate risk. The fact that more money is put into many mining districts than is taken out is notorious. Also, should a man buy all the tickets at a raffle the prize he would get would seldom pay him for his trouble. It is too often the same with a mining district. I say again that any mining engineer that flirts with chance when estimating positive ore in a mine is making a big mistake. That is admitted by all. When he allows chance to figure in his estimate of positive ore in a district he is making what may be a much bigger mistake. That should be admitted by all. When we take a chance that national reserves are so great as to be inconceivable, the loss affects every Canadian, and the present strangling taxation for unnecessary railways is proof of this.

Furthermore there is no need to take these chances. When estimating the reserves of a mine we can make deductions and call them probabilities or possibilities as the case may be. We can do the same with Cobalt reserves or the national reserves. The present system is sufficiently elastic. Rules of chance should be barred and the danger sign put up when dealing with reserves which we state are facts.

Mr. Mickle thinks that in Cobalt, "where mines showed possibly more ounces in reserve than were estimated for the previous year, notwithstanding several million ounces were taken out in the meantime," the rules of the text books should not apply. He asks, "Should that experience, occurring persistently, be ignored?" As a matter of fact that experience has not occurred persistently in Cobalt or anywhere else. The statistics I have quoted in another letter show that the Cobalt production has dropped enormously in the very brief period of the last dozen years. That implies ultimate exhaustion rather than persistency and is an argument in favor of close adherence to text book rules rather than any deviation.

Mr. Mickle thinks that if my method of reasoning were followed we could count on the collection of a mining tax for a few years only; in other words that we are not sure of any mining industry after our present reserves are ex-

hausted. Mr. Mickle seems to have missed the point, as I will try to show.

Mr. F. H. Mason has published a letter in which he states I have spoiled some perfectly good paper by printing curves which give a false impression due to the inclusion of war time statistics. If it will be of any satisfaction to Mr. Mason we will cut out the war time period altogether. The figures will then show an agricultural production of about \$1,200,000,000 as against a mineral production of about \$200,000,000, or a ratio of 6 to 1. Dr. Corless has stated that this ratio will not only be evened up but that mining will be supreme. Dr. Corless speaks of the future as the time when this will come about. This is very indefinite. If his claim means anything at all it will have to be realized in the immediate future. The agricultural production is growing and if the slack, or most of it, is not taken up very shortly the ratio will soon be 12 to 1 or worse. Instead therefore of Mr. Mickle trying to prove that our present production is going to be maintained, which I admit is quite probable, it is up to him to show, by the rules of chance, where it is going to increase 600 per cent.

This means that instead of one Premier Mine there will be six and each will continue present production indefinitely and not merely work out a high-grade zone and then shut down, as was the case with the Dolly Varden. Instead of the Granby, Britannia and Consolidated operating in British Columbia there will be 18 companies of this type and it is presumed they will all pay adequate dividends regularly instead of once in a while as has been the case to date. Instead of the British Columbia coal output decreasing as has been the program for the past ten years, it is now going to increase 600 per cent. Either these things will have to come about soon or other mineral developments must take their place. There is no indication of this on any appreciable scale.

This program may be figured out for each province. In Mr. Mickle's province the non-metallic and structural material production is to be increased six times and the output marketed. Instead of having the largest gold mine in the world that proud province will have the six largest. There will be six Cobalts. The three large nickel companies, that have been mining out our nickel ore as fast as possible, will be reinforced by 15 more and the 70 millions of tons at Sudbury will be cleaned up in a short time. The fact that this is the only important nickel area that has been discovered in Canada in 40 years and the only deposit of its class that has been discovered in the entire world in all time does not worry Messrs. Corless and Mickle. It is quite possible, I admit, that other nickel bodies may be discovered in the pre-Cambrian, but if our nickel resources are to be cleaned up at the rate indicated, and that rate maintained, ordinary engineering and conservation rules demand that other nickel bodies should now be in an advanced state of development. I have dwelt on nickel as it is our outstanding mineral deposit. The same remarks apply, in a greater degree, to our other minerals.

This is not, therefore, a question as to whether or not we will continue plugging along at the present rate of production, with our ups and downs, and showing on the whole a slight increase. Dr. Corless did not consider this

in his telegram or address. He has not considered it since. He is dealing with the Inconceivable as a Fact; with a mineral production that will make mining Canada's greatest industry. The above gives some idea of the order of the increase needed just to equal the agricultural production as it now stands. The claims of Messrs. Corless and Mickle seem to me to be reduced to an absurdity.

Since my return I have also read two utterances from outstanding sources which show that Dr. Corless' statements of fact are being accepted at their face value by the Canadian people.

The annual report of the Canadian Bank of Commerce features Dr. Corless' claim that "85 per cent of Canada will find its greatest economic future in its minerals." Dr. Corless' figures are based on the inclusion of the entire pre-Cambrian. I have discussed this in the August "Bulletin" and it appears to me that this proposition is a gross exaggeration. The Survey publications state that the mineral wealth of the pre-Cambrian is virtually confined to the Huronian, Keewatin and Hastings-Grenville formations. In other words the Laurentian, consisting of granites and granite-gneisses, shown in pink on all geological maps, is not essentially a mineral-bearing formation; yet Dr. Corless says that in this area the "principal or only basic industry is or will be mining." This Laurentian produces a large amount of timber, fish and furs and should continue to do so indefinitely. It contains valuable water powers, and some day part of it may be the home of large numbers of reindeer as it is now the grazing ground of millions of caribou. It is the dominating formation in the pre-Cambrian as it covers well over a million square miles on the Canadian mainland along or over one-third of our entire area. Statements regarding its mineral resources have a vital bearing on the situation. If the pre-Cambrian were made up entirely of Huronian, Keewatin and Hastings-Grenville, Dr. Corless might have some excuse for the proportion he uses, but adulterated as it is with the huge area of Laurentian there is no excuse for the statement what ever.

The other utterance to which I referred is one made by Sir Henry Thornton in his recent addresses to the Canadian Clubs. As quoted in the press it is as follows: "There exists in the West a mineral development which in importance will in time fully equal, if not excel, the possibilities of agricultural development." This is obviously inspired by Dr. Corless' address. If Sir Henry takes "Inconceivable Wealth in Minerals" as one of the first principles of Canadian railroading he is not going to make a much better success of his work than his predecessors. If we were justified in saying that we had wealth of that character, there was no need to send to the mother country for Sir Henry.

I do not propose to deal at length with Dr. Corless' letter, as I have already had ample opportunity to set out my case. Dr. Corless considers the information given in my letters emphasizes the soundness of his reasoning. This is reminiscent of the letter in which he dealt with Mr. McDougall's address. "Our mineral wealth is not inexhaustible," said Mr. McDougall. "Canada contains inconceivable wealth in minerals," says Dr. Corless. These statements constituted the gist of two addresses. They dealt with exactly the same thing—our mineral resources. One president said they are not inexhaustible; the next says they are. Dr. Corless then proceeded to prove to his own satisfaction that these statements were in entire agreement. The futility of further argument in a case like this is obvious.

There is, however, one correction I wish to make. Dr. Corless states that my "greatest fallacy" is "in the unwarranted

assumption that since we cannot estimate our national mineral resources as we do the developed ore in a mine, we are not justified in making any inferences as to their extent." My reply to that is that we *can* and that is the only proper engineering method to employ. I have started above and I have stated in other letters that this does not prevent us from making inferences, but that it does prevent us from making inferences in the shape of probabilities and possibilities and stating them as facts. There are too many reduction plants in Canada that should never have been built, were built before their time or were built on too large a scale—all due to inferences that were not warranted. I have referred to the extravagant construction of railways as one product of an era when belief in Inconceivable Wealth was orthodox. That belief has been a curse to this Dominion, yet Messrs. Corless and Mickle are doing their best to keep it to the front. Dr. Corless' message, in which he set forth what he considered to be the vital facts, dealt with Inconceivable Mineral Wealth as a Fact; "literally so great," he says, "that it cannot be conceived or imaged by the mind." That is the form in which it went forth and that is the form in which it is being relayed to the public by our leading organizations.

In the August "Bulletin" I pointed out error after error that Dr. Corless has made, yet he still insists that the chance of our having this Inconceivable Mineral Wealth is so great that it should be stated as a "fact." That old adage, "Be sure you are right, then go ahead" he now wishes to change, insofar as district and national reserves are concerned, to "Take a chance, then go ahead." The time has not yet come, and never will come, to make such changes in the basic rules of the profession as Messrs. Corless and Mickle stand for.

Canadians, at different times in their history, when they realized the facts, have given a remarkable account of themselves. In some cases it has been heroic. I have an idea they can do the same again if they are only allowed to wake out of that opiated dream of Inconceivable Wealth into which they have been lulled.

Cassidy, B. C.

## LETTERS FROM READERS

### Mr. Rainville on Argonaut

To the Editor,

"Canadian Mining Journal."

Sir, Regarding your editorial on "Argonaut" in your 16th inst. issue, I would say that it was unfortunate particularly for the prestige of the "Canadian Mining Journal," that such an article should appear. It savors throughout of the "cross roads gossip" and general lack of up-to-date facts, which might have been expected from such a source, and apparently was carefully selected to suit your purpose. You say that "the long expected reorganization of the Argonaut, Limited, has been postponed once more." By whom, may I ask, was this reorganization expected outside of yourself and one or two other parties who are continually inclined to the pessimistic side of the industry? You say that "it is time the facts of the case were stated publicly." Was this not done at the meeting of shareholders held at the Windsor Hotel, on the 17th inst? At this meeting there were over 300 shareholders present, representing over 75 per cent. of the stock, and they heartily and unanim-

ously approved of every detail of the method of financing, which was more or less the subject of your criticism. Probably if you had kept your editorial out of print a few days longer, you would have had nothing to say except that "the presence of copper pyrite in the ore makes the extraction of gold difficult and expensive, and faulting and other irregularities in the ore-bodies has resulted in abnormally high mining cost." This latter has been the wail of a few alleged mining correspondents for some time. After careful experimentation based upon the practice of the metallurgy of other mills treating such ore, (it might be well for you to note here that there are mills in other parts of the world successfully treating gold associated with chalcopyrite), the results were very satisfactory showing about 92 per cent. of the gold capable of recovery at the plant in the form of gold bullion and the remainder, 4 or 5 per cent., concentrated with chalcopyrite. The cost of this latter operation is insignificant compared with the results obtained and is but quite a minor operation in an average flow-sheet. As to "the faulting and other irregularities in the ore bodies", etc., I would say that this is another phrase which is overworked by the self-styled mining correspondent without having a fact or figure to substantiate it. I might say that there is no faulting problem unsolved at Argonaut today and that mining costs should not be abnormal.

It is, indeed, unfortunate that you were so ill-advised and poorly informed in regard to the Huronia deal. The facts of this deal were made public on the 17th inst., and I might say that Argonaut is in a position today to reap the benefit of 75 per cent. of the net earnings resulting from operations on what was originally Huronia ground. Argonaut has acquired also 17 additional claims towards the north and north east of the present workings with the main ore-body striking across this ground, and also has over 800 acres in Rouyn Township, Que., in a most promising location and showing encouraging gold values.

I think that it is "high time that your bluff was called", as the mining industry of Canada is bound to suffer through you and your mining gossip-mongers. It would be advisable that in the future for you to ascertain a few facts at least, before going into print and thus guard yourself from ridicule and humiliation.

J. H. RAINVILLE.

Montreal, Que.

## A PROMISING NEW PROCESS

### Gold, Silver, Lead, and Copper by Volatilization

The publication of Bulletin 211, "The chloride volatilization process of ore treatment," by Thomas Varley, E. P. Barrett, C. C. Stevenson, and R. H. Bradford, is announced by the Bureau of Mines, Washington: It is obtainable on request.

Chloride volatilization is defined by the authors as the process of separating or isolating certain metals from worthless gangue or other minerals by means of alkali or alkaline earth halides, such as common salt and calcium chloride, which are added to the prepared ores in proper amounts, treated in a suitably designed furnace at temperatures high enough to form and to vaporize or volatilize the chlorides of the metals present.

The exact chemical reactions are not definitely known. Vaporous chlorides of certain metals in the ores are formed and are drawn away from the heated charge into properly provided containers, where they are recovered by some suitable means.

### Process Still Experimental

The art of treating ores by the chloride volatilization process is still in the experimental stage. The process has not been sufficiently developed along metallurgical lines to warrant a definite statement as to the exact place it will occupy in the industry. The basic theory of the process has received the attention of prominent metallurgists for 20 years, and much research and experimental work have been carried on.

If commercially utilized, the process will fill a long-felt want in metallurgy, especially in the treatment of oxidized and semioxidized or "carbonate" ores of copper, lead and silver. Such ores are difficult to treat by gravity concentration or by flotation; in the former their tendency to slime upon crushing and their being of lower specific gravity than the sulphide minerals cause serious losses; in the latter much has been done in sulphidizing oxidized ores and subsequently recovering the artificial sulphides by flotation. Difficulties in proper sulphidizing and the low recoveries obtained have not balanced the cost of the treatment in many plants and in very few has it proved successful.

Evidently there is a big void to fill in the treatment of these ores. No radical changes in present methods are forecast, but it is obvious that chloride volatilization can have a distinct place as a method of treatment for ores that are not readily amenable to present methods. In many plants it might replace concentration methods, especially where part of the material content in the ores exists in forms other than sulphides.

### Clean Separation of Lead and Zinc

In addition to the minerals named above, gold in ores has been readily volatilized. Zinc does not form a volatile chloride, if an oxidizing condition is maintained in the roasting operations. Some excellent results have been obtained with carbonate-zinc concentrates containing silver and lead. Practically all the silver and lead were volatilized, but very little of the zinc. Experiments have proved that the process is probably one of the best for making a clean-cut separation of lead and zinc.

Not much work has been done on sulphide ores, because the need is pressing for a volatilizing method for treating oxidized and carbonate ores. Experiments on sulphides have been, however, encouraging. When the sulphur content is above 5 per cent a preliminary roast is usually necessary before chloride roasting and volatilization.

The experiments described in this bulletin cover part of the investigations carried on by the United States Bureau of Mines, in coöperation with the department of metallurgical research of the University of Utah, on ores from all parts of the United States. Large quantities of different types of ores not amenable to any other process were available, and the method developed gives promise of great commercial importance. A chapter by Stuart Croasdale on the development of the volatilization process appears in the bulletin.

## THE USES OF TALC

The United States is at present producing approximately two-thirds of the world's supply of talc, a mineral that enters into the making of an astonishing number of every day articles, states the Bureau of Mines, Washington, which has completed a study of the technical problems involved in the mining and utilization of this material.

### Paper, Paints and Gas Tips

Probably the largest single use of talc is as a filler or loading material in paper, according to Raymond B. Ladoo, mineral technologist in charge of the investigation. The manufacture of newsprint consumes the largest quantities, but talc is used also successfully in many papers, from the cheapest to the finest grades. For use in paper, talc must be procurable at a price about equal to that of the best white clay; but paper makers could afford to pay slightly more if the talc is retained in paper better than is the clay.

Talc has been used for a number of years as a filler in the manufacture of mixed or ready-prepared paints. At first it was used secretively and was regarded as an adulterant; but gradually by actual tests and impartial research it was found that talc had valuable properties that really improved paints used for some purposes. To-day paint chemists regard talc as a paint material of great value.

Although the uses of talc and soapstone are many and varied, few of them are considered as essential in the sense that no substitutes can be used, but several are of great importance. Massive, close-grained talc, free from iron and grit, is cut into blanks and baked, forming the material used for gas tips and electrical insulation, commercially known as lava. The hardness of lava, its resistance to heat, acids, and alkalies, and its great dielectric strength make it very useful for electric insulation, and no satisfactory substitute for it has been found.

### Foundry Facing and Toilet Powder

The widest use of talc is in the powdered form. The value of ground talc depends upon color (whiteness), uniformity, fineness of grain, freedom from grit, "slip," and sometimes freedom from lime. White talc, free from grit and iron, and low in lime, ground to about 200-mesh, is used largely as a filler for paper, rubber, and paint. Ground talc and soapstone are used for foundry facings, either alone or mixed with graphite. A coarser grade of talc is used in the manufacture of asphalt-coated roofing felts and papers, both as a filler and as a surfacing.

The highest grade of ground talc is used as toilet powder, whiteness, fineness of grain, freedom from grit and lime, and a good "slip" being essential. Ground talc is also used in dressing and coating cloth, in making soap, rope, twine, pipe-covering compounds, heavy lubricants, and polishes. Massive varieties of talc, pyrophyllite, and high grades of soapstone are cut into slate pencils and steel-workers' crayons. French chalk or tailors' chalk is a soft, massive variety of talc. In China, Japan, and India, massive talc is carved into grotesque images and other forms and is often sold as imitation jade.

Talc is a hydrous magnesium silicate; it is often called steatite, soapstone, or potstone, and by the trade names talc clay, agalite, asbestine, and verdolite. The

term talc may be used to include all forms of the pure mineral, whereas steatite denotes particularly the massive, compact variety, and soapstone the impure, massive form that often contains only 50 per cent of talc. Talc ranges in color from pure white and silvery white through gray, green, apple green, gray green to dark green, also yellow, brown, or reddish when impure.

Talc and soapstone, with pyrophyllite — usually sold as talc — are widely distributed over the earth. Deposits are known in nearly every country, but production on a commercial scale has been confined mostly to the countries having highest industrial development. Of the total for the world, the United States produces about 65 per cent, France 13.4 per cent, Italy 7.4 per cent, Germany and Austria 5.4 per cent, and Canada 4.7 per cent. Vermont has the largest known talc reserves of any producing state, over 7,000,000 tons being reported from two companies.

### Transportation Facilities Important

As talc is a relatively low-priced commodity and its distribution throughout the world is general, transportation and distance from markets have influenced the location of new plants. The largest use of ground talc lies in the manufacture of paper, and its principal rival as a paper filler has been English clay. Most of the paper mills in the United States have been in New York and New England, and thus the talc deposits of New York and Vermont have been most fully developed because more easily able to compete with English clay brought into the ports of New York and Boston. In addition, the other industries that are large users of talc have been concentrated mostly in the northeastern States. The most important deposits of talc of toilet grade in the United States are in California, Washington, and possibly in North Carolina and Georgia.

In the South the remoteness of the deposits from railroads, the poor roads, the moderate size of the veins and the lack of capital for improving transportation, for adequate prospecting and development, and for building efficient mills of large capacity, as well as the distance from the markets for medium-grade tales, have prevented the growth of the industry. Deposits of talc of commercial grade are known in numerous Western states, but many of them are remote from transportation.

The results of these investigations are given in Bulletin 213, "Talc and soapstone; their mining, milling, products and uses," which may be obtained from the Bureau of Mines, Washington, D.C.

## AUTOMATIC TEMPERING OF STEEL

The O'Donovan furnace for tempering drill steel automatically is described briefly and illustrated in the "South African Mining and Engineering Journal" for February 10th. It has been developed at the East Rand Proprietary Mines, and it is expected that its operation will result in perfectly tempered steel. It is estimated that the hand tempering methods now in vogue result in 30 per cent of the steel sent underground being faulty in temper, and the new method of automatic tempering is expected not only to eliminate these faults but to save a large fraction of the present consumption of drill steel. Mr. O'Donovan's method is based upon the fact that steel becomes non-magnetic at a certain temperature, and that this temperature is also the exact point best for tempering.

# The Mining Districts

BY THE JOURNAL'S CORRESPONDENTS

## QUEBEC

**TRANSPORTATION TO NEW GOLD FIELD.**— Rouyn township will be made easy of access before May 15th. Such is the substance of a statement given by Mr. Téspélère Simard, the very active member for Temiscamingue in the Provincial Legislature.

Mr. Simard was in Quebec this week to plead before the Minister of Colonization, Mines and Fisheries, the case of the Quebec prospectors for better communications between Ville-Marie and the new gold discoveries in Rouyn township.

Mr. Simard, who spent the first two weeks of March in Rouyn township in the performance of his professional duty as a Land Surveyor, was very much pleased with the earnestness displayed by the different syndicates now prospecting in the district. Diamond-drilling by the Hammell-Bryce interests on the Robert Cockeram claims is going on actively. Six camps have been built during the winter by the Noranda Mines, Limited, on the Powell claims. Shaft sinking equipment is on the ground, and by April 1st. forty men will be engaged on development work.

The greatest handicap of the Rouyn camp to-day is inaccessibility. However, in view of the importance of the rush and of the development work already started, the Minister of Mines, Mr. Perrault, has expressed his eagerness to help the prospectors by all the means at his disposal. When Mr. Simard left Quebec after a busy week at the Parliament buildings, he had the assurance that the opening of two different routes will be assisted. One, an all-water route, will be ready immediately after the break-up on Lake des Quinzes; the second will be partly over land, making use of the 15-mile stretch of still water on Lake Opazatica.

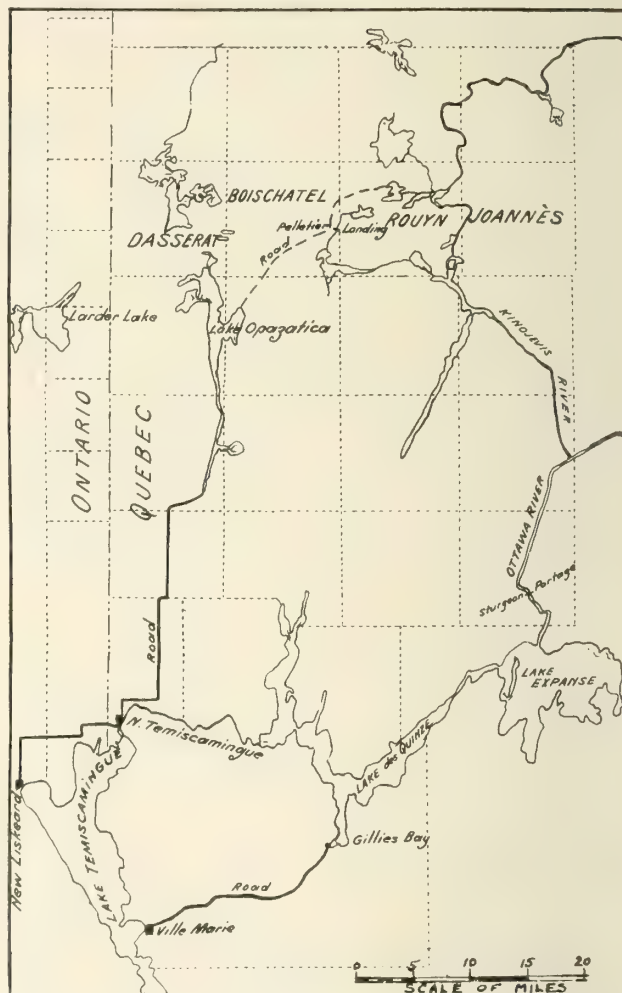

The Minister of Mines has made a grant to the Ville-Marie Navigation Company to organize a regular boat service from Gillies Bay to Boischatel, Rouyn and Joannès townships. It is expected that by May 15th a motor boat will be making regular trips. During the summer months supplies leaving Ville-Marie on motor trucks at six o'clock in the morning will be unloaded on Pelletier river by six o'clock in the evening, or twelve hours later.

From Ville-Marie as a starting point, one will journey to Gillies Depot, a distance of 24 miles over a good automobile road. From Gillies Bay a 65-foot motor-boat will carry passengers and freight over Lake des Quinze and Lake Expanse, to Sturgeon portage on the Ottawa river, the only stop of the whole journey. Above the portage a gasoline launch will take the load up the Ottawa river, the Kinojevis river, Lake Kinojevis, Lake La Bruyère, Lake Senezergues and up the Pelletier river as far as the rapids. The landing will be near the boundary line between Rouyn and Boischatel and will be near the center of the promising discoveries.

Besides the Ville-Marie Navigation Company, who will run a regular service, there will be other owners of motor boats who will make it a business to carry passengers and freight over the same route.

The second, or Lake Opazatica route, which eventually will be a permanent route, will be ready only by next fall, as a considerable amount of work has to be performed on it.

Starting from North Temiscamingue, sixteen miles from New Liskeard, the road through Nedelec township to Lake Opazatica, a distance of 23 miles will be reconstructed and made a first-class automobile road. The fifteen-mile stretch of water of Lake Opazatica will be made use of, and a motor boat will ply be-

tween the lower end of the lake and the northern extremity of East Bay. Thence a waggon road, seventeen miles long, will be cut through the bush in a north-eastern direction to the mining center of Rouyn township.

The Rouyn rush has not yet reached its peak and already 86,000 acres have been staked for mineral rights in that and adjoining townships. Requests for Prospector's Certificates at the Ville-Marie agency since January 1st, have come in larger number than at the head office in Quebec. In view of the large number of recorded claims that will follow, the Minister of Colonization, Mines and Fisheries has adopted the view of the men on the field, and a claim recording

office will be opened in Ville-Marie at a very early date. A competent officer from the Quebec office will take charge. This departure in the administration of the mining law of Quebec will be welcomed by the prospectors who since last fall have asked for such decentralization.

The organization of means for the fast transportation of men and supplies into the camp, and the establishment of a recorder's office at such an important town as Ville-Marie, shows that the Quebec Government is solicitous for the development of the mineral resources of the Province.

## NORTHERN ONTARIO

**BRANCH RAILWAYS ADVOCATED.**—The newspapers and mining interests of Northern Ontario are strongly advocating a branch line of the T. & N. O. Railway through the Kirkland Lake and Larder Lake field to the Quebec boundary, where a large amount of mining development is under way. In a recent issue of the "Northern Miner" it was pointed out that the extension of the T. & N. O. north of Cochrane is claimed to be partly for the purpose of serving a mining district. The "Northern Miner" map, however, shows that there are only eleven mining claims in good standing along the line of the northern extension, while there are thousands of claims and a large number of producing mines along the proposed Kirkland extension. The Ontario Government has not built a single mile of railway to serve the mining districts for over ten years, and the growth of the industry certainly demands more consideration. There is also a proposal to build a branch from Cobalt to South Lorrain, and this is a matter that warrants serious consideration on the part of the Government. South Lorrain has made remarkable strides during the past year and is now one of the important silver camps on this continent. During the first three months of 1923 the Mining Corporation property there will produce 500,000 ounces while the Keeley, shipments in March alone are expected to amount to 400,000 ounces. The president of the Mining Corporation, at the annual meeting of that Company, stated that they were very enthusiastic regarding the possibilities of the Frontier mine and that the engineers predicted a long life. It is hardly to be expected that production will be confined to the two properties above mentioned, and the district appears to have ahead of it many years of life as an important producing centre. At the present time in Cobalt there are several mills that will have shortly an excess capacity and it would seem an economic waste to duplicate these milling facilities in South Lorrain. If a railroad were to be built into South Lorrain and a freight rate of approximately \$1.00 a ton given on ore, it is probable that the greater part of the production in that district would go to Cobalt for treatment.

**LARDER LAKE.**—The Crown Reserve has cut a station at the 550-foot level of its shaft at Larder Lake (sometimes called the Pancake Lake property) and is now cross-cutting to the vein, which will be intercepted at a distance of about 275 feet from the shaft. Underground developments continue to confirm previous reports regarding widths and assays and further confidence is inspired by the results of the work on the Associated Goldfields property, only a short distance from the Crown Reserve line. The Company will fi-

nance future developments by the issue of additional stock, which was ratified at the recent shareholders' meeting, and it is understood that no attempt will be made to float a bond issue.

**COBALT.**—The annual report of the McKinley Dargagh shows a mining profit of \$103,035. The properties were only operated for six months of the year and the shut-down expenses were \$37,967, leaving a net profit of \$65,086. Production was 297,033 ounces. Cash assets stand at \$239,800. 20,000 tons are broken in the stopes and there is a considerable tonnage of unbroken ore to be mined. The tailing plant was not operated in 1922. Unless the price of silver declines it is anticipated that a fair profit can be obtained from operating the mill this year.

**ARGONAUT.**—Officials of the Argonaut have made a reply to some recent criticisms of that property that appeared in this journal. The property is under excellent management and from such information as can be obtained in that part of Ontario, appears to have good possibilities of being successful.

**NORTHWESTERN QUEBEC.**—R. H. Lyman, of Cobalt, has taken an option of 1500 acres in the new Quebec district on behalf of American associates. Sufficient finances have been arranged to permit of a thorough exploration of the properties and supplies have already been sent in. Other Cobalt companies are investigating the possibilities of the field, and it is expected that several of them will be active in Northern Quebec this year.

**PORCUPINE.**—The Goldale has decided to sink its shaft from the 500 to the 1000-foot level. Geologists seem to be of the opinion that the McIntyre section is covered by a lava cap, and that greater depth offers excellent possibilities. On the 500 ft. level a shoot of commercial ore was drifted on for a length of over 200 ft. with an average width of approximately 8 ft. To date the Kerr Lake has spent approximately \$100,000 on the property and it is expected that another \$75,000 will determine the commercial possibilities of the property.

Underground developments at the Peninsular continue favourable, and on the 425-foot level, 150 feet of drifting has shown an average of approximately \$13 for a width of 9 feet. It is understood that the company diamond-drilled about 1,000 feet away from the workings and picked up the continuation of the vein, which gave good values.

**COBALT DEVELOPMENTS.**—At the Ruby property in Cobalt, which is under option to the Coniagas, a long crosscut is being driven to explore the possibilities of the conglomerate underlying the diabase. In the month of February a total of 212 feet was driven in one heading, which is exceptionally fast work considering the limited number of men employed. La Rose and Colonial are continuing their shafts, the Colonial now being down over 930 feet, which must be very close to the contact. The La Rose shaft was down 475 feet on April 1st, making a footage of 125 feet for the month.

**MATACHEWAN.**—The Matachewan Canadian Gold Mines has been reorganized in order to take in several other properties. The capital is now \$5,000,000 of \$1.00 par and of this \$3,330,000 is paid for properties and services rendered, leaving \$1,670,000 shares in the treasury. The public will no doubt be asked to put up the money for this minority interest. Considerable work has been done on one of the properties and it is estimated that some ore has been developed, but the

These properties are understood to be practically unexplored and it is much too early to hold out any definite promise of having a commercial venture.

Senator G. D. Robertson, formerly Minister of Labour, is the president of the company and speaks very enthusiastically about it. It is unfortunate that members of the Government should lend themselves to promotions of this sort. The venture may be justified, but preparations are believed to be under way for a stock-selling campaign in which Senator Robertson's position in the Government will no doubt be used as a selling argument with unsophisticated investors. Senator Robertson, as Minister of Labour, was not remarkable for discretion, and his entry into the realms of mining finance is not likely to add to his prestige.

### BRITISH COLUMBIA

**SMITHERS.** — To acquire a prospect in July and six months later to have succeeded in carrying development to the point that the shipment of four cars of ore, 140 tons in all, is possible is something of an achievement. When it is known that this ore carried an average of 200 ounces of silver to the ton besides lead, it will be appreciated that these energetic and well directed efforts have not been in vain.

The property in question is the Henderson group, Hudson Bay Mountain, northern British Columbia; the man chiefly responsible for the results so far shown is J. F. Duthie, of Seattle; and the precise location of this development is 227 miles inland from the Pacific coast near the town of Smithers on the line of the Grand Trunk Pacific Railway.

Mr. Duthie and his associates control, besides the Henderson, the Mamie, Dome and Raven groups, all situated on the slope of Hudson Bay Mountain, which lies a few miles to the northwest of Smithers and rises to an altitude of some 8,500 feet.

The Mamie group, was developed first by drift tunnel and winzes. Its future will depend largely on a crosscut tunnel now being driven, upon which work was stopped when winter set in. A compressor and water wheel have been installed.

The opening up of the Henderson group, has been carried on steadily since last July. Surface work and drift tunnels have partly developed two veins, known as the "grey copper" and "ruby silver" veins. The latter has been exposed for about 500 feet by the lowest tunnel, which is in 700 feet. From this tunnel stoping has been started and it is expected that shipments can be maintained. It is planned that the "grey copper" vein shall be cross-cut and its products handled from this level.

The Henderson at present is equipped with two small portable gasoline-driven compressors which operate two stoping drills, one tripod drill and a pneumatic drill sharpener. It is understood that a 10-drill compressor will be taken in as soon as weather conditions permit.

The continuance of the work on the Mamie, the opening up of a third vein on the Henderson, and the exploration of the Dome and Raven claims is proposed for this summer. To carry on these operations a considerable amount of new plant is to be purchased.

There is a good reason to believe that all this presages the establishment of a permanent and prosperous mining camp. In close proximity to the properties

mentioned is the Victory, which has been under development on a small scale for some years with encouraging results. In addition to the high-grade ore found on the two veins of the Henderson now being worked, there is a considerable amount of milling material. The owners, too, are satisfied that their work on the Mamie, Dome and Raven groups, which is to be conducted with vigor this year, will bring the reward sought.

**MARBLE BAY MINE.** — A report that the Anaconda Copper Company has purchased the Marble Bay Mine, Texada Island, British Columbia, although lacking official confirmation, has created a flurry of interest in provincial mining circles.

This mine was operated practically continuously from 1897 to 1920 producing some 10,000 tons a year. A large interest was held by the Tacoma Smelter Company, although there are understood to have been other major shareholders, among whom was the late H. W. Treat, a well known promoter and capitalist of Seattle.

In 1911 Herbert Carmichael, Provincial Assayer, reported that the main shaft had been sunk to the No. 10 level, 863 feet below the surface and that "from the bottom of the shaft drifts run both to the north and the south. On the northern drift, 160 feet from the main shaft, No. 2 Shaft has been sunk and is now within 6 feet of the No. 13 level, or a distance of 1,157 feet from the surface." Stoping and development work, he stated, were in progress in nearly all the levels, "the biggest stopes being on the No. 11 level, and the greatest amount of ore being taken out between No. 11 and 12 levels."

The ore is a mixture of bornite and copper pyrite in a felsite gangue. High-grade bornite was taken from the lowest level although it was thought in the earlier stages of development that it would give place to copper pyrite.

Mr. Carmichael continues: "The ore is found in a

light colored felsite, more particularly where the latter runs into the limestone country rock; ore also is found in pockets of actinolite and sometimes associated with garnetite, though as a rule where the latter is found there is no ore. There is little to guide the management in prospecting for new ore-bodies, as all the felsite shoots do not contain ore. A little ore may show up in a drift and may open out into a large and profitable ore-shoot while, again, a good showing may be blown out in a few shots. Diabase dykes occur all through the mine, but these appear to have been formed prior to the felsite dykes, as pieces of the former seem to have broken off and fallen into the felsite when it was formed, the diabase retaining all its angular corners.

"Taken in conjunction with the mineralogical conditions disclosed by recent work on the 'Little Billie' [a mine close to the Marble Bay,] there is increasing evidence to lead one to the belief that the felsite dykes carrying the ore solutions had their origin in the great granite flow noted on this part of the Coast, this rock being the most recent in the series, and that the basic materials were held in solution until they were precipitated where the felsite came in contact with limestone."

This gives a good idea of the property and the problem those directing its exploitation had to face and overcome. The values, however, were high and persistent, although not altogether consistent throughout the ore zone. Throughout the intervening years up to and including 1919 the Marble Bay Mine continued to be an important producer. Then the copper market sagged and, although the later underground development promised more of the same sort of ore-bodies that had in the past been so satisfactory in their yield, it was not thought to be economically sound to continue and operations ceased.

The last official report on the Marble Bay, written by Wm. M. Brewer, resident mining engineer in the 1918 report of the Minister of Mines, was optimistic in its tone. It says in part:

"The development work during 1918 has been confined almost entirely to opening up the 1600-foot level, which is about 1500 feet vertically below the surface and about 1400 feet below sea level. Diamond drilling has been done to explore the ground below the 1600-foot level on the westerly side of the incline winze from the 1500-foot level. These drill holes show large bodies of garnetite; one of these bodies is shown to be persistent for about 100 feet in a hole bored on a 26 degree angle from the floor of the 1600-foot level. The core also shows some narrow stringers of bornite in the garnetite."

The accompanying sketch shows how erratic the ore bodies have been in their occurrence and yet, Mr. Brewer observes, "when the formation is carefully studied there is a certain regularity and indications that, when followed, result in the discovery of extensions of the known ore-bodies or in finding new ones."

#### GOLD CLAIMS OPTIONED

James F. Flynn has secured an option on the Manley-O'Reilly claims in Skead township, northern Ontario, on which some spectacular showings of gold have been found. Mr. Flynn has let a contract for a shaft 100 feet deep, and as soon as weather permits will conduct surface exploration under his personal supervision.

#### NOVA SCOTIA

**WAGES INCREASED AT SYDNEY.**—On Wednesday, March 27th, a notice was posted at the Sydney Steel Works, granting a general increase to all classes of workers. The increase ranged from 10 to 14 p. c., the lower classes receiving 12 or 14 per cent, as required to bring them up to a living wage. This is in keeping with the statement made by President Wolvin some time ago, that "if orders were procured at better prices, the workmen would share from the beginning." The following statement was made by the Company: "The Management desires to point out that the Plant is being operated at a loss, and that a new scale of wages would substantially increase the loss. Since March 14th, some classes of the Company's products have been sold at better prices, and indications now are that conditions in the steel trade will continue to improve for some months to come.

"We realize the cost of living and the long period of partial employment in Sydney. On this account, and in the hope that we may as rapidly as possible fill the unprofitable orders now on our books, and thereafter be able to take new business at the better prices now prevailing, the Company is prepared to assume the additional loss, that a wage increase entails, and to put an increase into effect earlier than trade conditions actually warrant.

"Special consideration has been shown to such ordinary labor rates as are now below thirty cents. These classes will be increased 12 to 14 p.c."

Just what action will be taken by the workmen is not in much doubt of the labor leaders, under the stimulus of the Workers' Party of Canada, are to be taken seriously. The inflammatory, offensive and threatening speeches made by these men in Sydney during the last six months bore fruits of their kind in February last, and are sure to have greater and worse results when a genuine issue is at stake. Were the steel workers of Sydney left to their own opinions, they would gladly accept the offer of the Company and would trust them to give further help in the future when business improves. But the Workers' Party have stated that their policy is to take advantage of all such situations to advance their cause, and where conditions are favorable to strengthen themselves that they may ride rough-shod into power.

**BOARD OF TRADE'S STAND.**—The business public of Sydney are fully alive to the seriousness of the situation, and the Board of Trade has taken a stand in the matter. After first resolving to stand together for law and order, they then appealed to the Governments to help the right thinking people of Cape Breton to wipe out Bolshevism. Should rioting begin with a strike, it is their intention to step into the gap and hold the fort until relief arrives. Some such heroic stand is most necessary, and the Board of Trade seems to think that it is the proper body to take it. In the election that took place a few weeks ago, the Reds were swept from the council board, and the Moderate candidates were put in control of the administration of the city. The authority is now in their hands, and they are called upon to enforce the law and assert the rights of the people. The workmen will have the right to strike, but not the right to keep others from going to work who want to do so.

Private property will be protected, and the liberty of every Canadian citizen safeguarded. For long the

and industry has languished on an ebb tide, and now that the flood has set in the citizens of Sydney will conduct their affairs in such a way that it will lead to fortune rather than to misery. In this they will be loyally supported by the general public of Canada.

**TIME-OUT FOR THE REDS.**—The coal industry of Nova Scotia, through the effect of the long strike in the United States, has prospered during the last six months. Steady employment at good wages has been general in the collieries. Very little complaint was heard. To all appearances the miners had got down to work with a will, and it was beginning to be generally felt that peace and prosperity were again walking hand in hand. But just as soon as the steel workers issued their ultimatum recently, special Sunday meetings were called at the collieries, and grievances unknown and unheard of were publicly aired. Many of the complaints were ridiculous.

It was noticeable that at some of these meetings, the editor of the "Labor Herald" and James B. McLaughlin were present, and from the suddenness of the outbreak it is apparent that the agents of the "Workers' Party" had been active in each local. The policy of this party is to interrupt industry, and by means of the uncertainty of business to break down the present industrial system. The main purpose at present is to worry and irritate the Company while the pending steel strike is on, and force their hands and at the same time advance the cause of the Reds. They may succeed better than they anticipate, for such continuous interference may bring about a cessation of all the Company's industrial activities.

**THE NOVA SCOTIA COAL TRADE.**—The remaining months of this year should witness great activity in the coal trade of Nova Scotia. A considerable amount of coal has been sold in the New England States this winter; but when the Americans catch up with the demand of their own coal trade, this territory is not likely to be open again for our coal for many years. The large outputs of American mines in normal times more than supply their own trade and the overflow will undoubtedly find its way into Canadian markets, thus competing with Nova Scotia coal. The present prosperity is not, therefore, due to any increased demand in the Canadian market, but to a scarcity in the markets of our neighbors. Those who know the coal trade view with more or less anxiety the competition to be faced in the near future. Formerly wage agreements provided stability in the coal industry, but of late public confidence has been rudely shaken in any contract entered into between the District No. 26 and the Dominion Coal Company.

**EMPLOYMENT GOOD.**—A feature that both the steel and coal workers fail to see is the general state of employment now prevailing in Cape Breton in both the steel and coal trades. This is all the more remarkable when compared with conditions in other industrial centres of the province. Perhaps there is no part of Canada just now where employment conditions are so favorable. There is no unemployment at the collieries and except for some idle time in the Sydney Mines district at one or two collieries owing to car shortage, miners are well employed. Sydney is almost in the same favorable condition. Statements have been sent broadcast over Canada and to Great Britain that labor is scarce and many men are out of work. There is little truth in such vaporings. They are made for the purpose of prejudicing the public mind against the British Empire Steel Corporation. Hundreds of out-

side men have found employment at the collieries since last fall and are well satisfied with the conditions.

**HEARING OF STEEL WORKERS' COMPLAINTS.**—Mr. E. McG. Quirk, representing the Federal Labor Department, spent a few days in the Sydney district, gathering information on the labor situation. He met officers and delegates of the steel and coal labor organizations and discussed conditions with them. The steel workers were very outspoken and made no attempt to conceal their case and their intentions from Mr. Quirk. When the statement was made that the steel workers were not organized, and could not enforce their demands, Mr. Quirk was openly told that if proof were necessary, a two hours' demonstration would be given by calling out the workers of any department of the steel works he wished to name. The temper shown by the men of the steel plant is determined. They believe they can win a strike within a week by withdrawing the maintenance men. They are not ignorant of the fact, however, that if the strike drags on and the company are able to keep the coke-ovens and the blast-furnaces warm, they stand to lose a strike. Should they succeed in keeping men away from the coke-ovens until these cool off, they will lose in any case. It cost \$2,000,000 to build the ovens and it took one year to complete the work. Capital has lost all confidence in the workers of the coal and steel industry of Cape Breton, and it might be many years before it could be induced to venture back again.

On account of the information, thus openly given to Mr. Quirk, it may be that the stated object of the strikers in trying to render the property of the Company useless will be frustrated. It is known now that steps have already been taken to safeguard property and to keep the blast-furnaces and the coke-ovens warm in the event of a strike.

## POSITIONS OPEN AT OTTAWA

The following positions have been announced as open for application until April 19th by the Secretary, Civil Service Commission, Ottawa. Application forms can be had from the Secretary, from any office of the Employment Service, or from post-offices in the principal cities.

**5149** — An Assistant Geologist, Geological Survey, at an initial salary of \$2,100 with annual increase of \$120, and in addition whatever bonus may be granted by law. The duties are general geological mapping and similar work. The qualifications include graduation and two years post-graduate work in geology and mineralogy, and two years of field training.

**5150** — An Editor, grade 1, Editorial Division, Department of Mines, at an initial salary of \$1,800 with annual increase of \$120, and bonus as provided by law. The duties are to edit, under instruction, the publications of the department. The requirements include graduation from a university or its equivalent, two years' experience in editing work, and a general knowledge of the technical operations conducted by the Department of Mines.

South Africa has produced to date £1,053,000,000 in mineral wealth. Three quarters of this, or £748,000,000, was contributed by gold, and £222,250,000 by diamonds. More than 90 percent of this gold has come from the Witwatersrand.

of Canada, Limited**Hamilton, Ont.  
Montreal, Toronto, Winnipeg, Seattle**PURCHASE OF GOLD ORES**

The attention of prospectors and others is drawn to the provision in the Mining Act of Ontario authorizing the Department of Mines to purchase parcels of gold ore taken out by prospectors and others in developing or working mining claims. Arrangements have been made by which such parcels of gold ore, whether large or small, will be accepted by the Timiskaming Testing Laboratories at Cobalt, and paid for according to the schedule provided for the purpose. The Laboratories are operated under the auspices of the Department of Mines.

This offers a first class opportunity for testing the value of ores on a large scale, and also of turning ore of good quality into money for carrying on further development work. By special arrangements, on less than carload lots, freight rates on the T. & N. O. Railway are reduced 50 per cent.

The Laboratories are also equipped for working out the best methods of treatment for gold or silver ores of a refractory or unusual character.

Full information as to treatment charges, schedule of payments, etc., can be obtained from the undersigned, or from A. A. Cole, Manager, Timiskaming Testing Laboratories, Cobalt, Ontario.

THOS. W. GIBSON,  
Deputy Minister of Mines.

# MORSE CHAINS

A few of the Morse chains in use at the Raymond Lead plant

Using chain drives speeds up production, cuts belt expense and overtime wages and operates with practically no repairs.

CANADIAN AGENTS

**Jones & Glassco, Regd.**

MONTREAL, TORONTO.

Write for Booklet

O. W. Ludwig, Plant Superintendent of the Raymond Lead Co., Chicago, says:

"Thirteen years of service without a repair is our experience with two 100 H.P. and ten 20 H.P. Morse Silent Chain Drives.

"When we moved into our present plant thirteen years ago, we installed the present Morse equipment of silent chains for our two lead mills and ten hydraulic pumps. We had always previously used leather belts, but not without considerable trouble. For instance, if the operator was not careful—and gave the motors too great a load, the leather belt would slip and in some cases burn out. While with the Morse Chain Drive we overload them at times up to 15 H.P. without the slightest trouble.

"When we used leather belts on the hydraulic pumps, if a pump packing suddenly gave way, the water would squirt all over the pump as well as adjoining pumps, causing the leather belts to get wet. This often necessitated a shut-down on 3 to 4 pumps to dry out each belt, thus causing a loss of time by the men, which resulted many times in paying overtime to catch up on the work. Of course, with our Morse Chain Drive we have no such trouble—this positive drive prevents slippage and is not affected by water.

"Leather belts lasted us 2 to 3 years at the most, while our Morse Chain Drives have already lasted 3 to 4 times that long and seem good for many more years. So Morse Drives have cut our expense materially, speeded up production, cut out overtime wages and saved floor space, for they operate on shorter centers."

## INDEX TO MINE AND MILL SUPPLIES

Addresses of advertisers whose names appear in the following classified index, may be found upon reference to their advertisements. An alphabetical index to advertisers will be found on the page facing the inside back cover. The following regulations apply to all advertisers:—One-eighth page, every issue, three headings; one-quarter page, every issue, six headings; one half page, every issue, six headings; one half page, every issue, twelve headings; full page, every issue, twenty-four headings. Buyers who are unable to find in the classification heregiven such machinery or supplies as they desire are invited to write Service Dept., Canadian Mining Journal, Gardenvale, Que., who can in all probability, refer them to proper sources.

## MINES BRANCH

Department of Colonization, Mines and Fisheries

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, etc.

### MINISTER OF COLONIZATION, MINES AND FISHERIES, QUEBEC

**MINER'S CERTIFICATES.** First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is \$10 and is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

**WORKING CONDITIONS.** During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

**SIX MONTHS AFTER STAKING.** At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

**MINING LICENSE.** The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year, and a fee of \$10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days' labour on each forty acres.

**MINING CONCESSION.** Notwithstanding the above, a mining concession may be acquired at any time at the rate of \$5 an acre for SUPERIOR METALS, and \$3 an acre for INFERIOR MINERALS.

The attention of prospectors is especially called to the territory in the North-Western part of the Province of Quebec north of the height of land, where important mineralized belts are known to exist.

**PROVINCIAL LABORATORY.** Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, Montreal, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The bureau of Mines at Quebec will give all the information desired in connection with the application for mining concessions of the Province, on application addressed to

**HONORABLE J. E. PERRAULT,**

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

# BRITISH COLUMBIA

## The Mineral Province of Western Canada

Has produced Minerals valued as follows Placer Gold, \$76,542,203; Lode Gold, \$109,647,661; Silver, \$59,814,266; Lead, \$51,810,891; Copper, \$170,723,242; Zinc, \$24,625,839; Coal and Coke, \$238,289,565; Building Stone, Brick Cement, etc., \$36,605,942; Miscellaneous Minerals, \$1,358,839; Making its mineral production to the end of 1922 show an

### Aggregate Value of \$734,259,619

The substantial progress of the Mining Industry of this Province is strikingly exhibited in the following figures, which show the value of production for successive five-year periods: For all years to 1895, inclusive \$94,547,241; for five years, 1896-1900, \$57,605,967; for five years, 1901-1905, \$96,509,968; for five years, 1906-1910, \$125,534,474; for five years, 1911-1915, \$142,072,603; for 5 years 1915-1920 \$189,922,725; 1921, \$28,066,641; for the year 1922, \$35,158,843.

### Production During last ten years, \$339,280,940

Lode-mining has only been in progress for about twenty-five years, and not 20 per cent. of the Province has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those of any other Province in the Dominion, or any Colony in the British Empire.

Mineral locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with Mining Reports and Maps, may be obtained gratis by addressing.

VICTORIA, British Columbia.

- Summary Report of the Mines Branch, 1920.  
The Mines Branch maintains the following laboratories in which investigations are made with a view to assisting in the development of the general mining industry of Canada:—
- Fuel Testing Laboratory.—Testing value of Canadian fuels for steam raising and production of power gas; analyses, and other chemical and physical examinations of solid, liquid and gaseous fuels are also made.
- Ore-Dressing Laboratory.—Testing of Canadian ores and minerals, to ascertain most economical methods of treatment.
- Chemical Laboratory.—Analysing and assaying of all mineral substances and their manufactured products. Copies of schedules of fees, which are slightly in excess of those charged by private practitioners, may be had on application.
- Ceramic Laboratory.—Equipment is such that complete physical tests on clays and shales of the Dominion can be made, to determine their value from an economic standpoint.
- Structural Materials Laboratory.—Experimental work on sands, cements and limes is also undertaken.
- Applications for reports and particulars relative to having investigations made in the several laboratories should be addressed to The Director, Mines Branch, Department of Mines, Ottawa.
- Summary Report. The annual Summary Report of the Geological Survey is now printed in parts. Applicants should, therefore, state what particular geologist report is required, or what subject they are interested in.
- Memoir 108. The Mackenzie River Basin, by Charles Camsell and Wyatt Malcolm.

# Ontario's

# Minerals

PROVINCE OF ONTARIO

DEPARTMENT OF MINES

HON H. MILLS, Minister of Mines

## Mineral Areas.

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favorable for the occurrence of minerals, 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver mines of Cobalt occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

## Economic Minerals.

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario:—actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluor-spar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, portland cement, brick and tile, meet every demand.

## Mineral Production.

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1921 to be worth \$48,128,387, of which the metallic production was \$27,574,202.

The following figures show the rapid growth of Ontario's mineral industry by five-year periods since 1891:

| Year.          | Value.      | Year.          | Value.       |
|----------------|-------------|----------------|--------------|
| 1891 . . . . . | \$4,705,672 | 1906 . . . . . | \$22,388,383 |
| 1896 . . . . . | 5,235,003   | 1911 . . . . . | 41,976,797   |
| 1901 . . . . . | 11,831,086  | 1916 . . . . . | 65,303,822   |

## Dividends.

Dividends and bonuses paid to the end of 1921 amounted to \$23,140,734 for gold mining companies, and \$84,388,185 for silver mining companies or a total of \$107,528,919.

## Mining Regulations.

A miner's license costs \$5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of \$2.50 or \$3.00 per acre, depending on location in unsurveyed or surveyed territory.

## Assay Office.

The Provincial Assay Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

## Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

## -:- EDITORIAL -:-

### PUBLICITY OFFICER FOR MINING REQUIRED

The mining industry in Canada needs well-directed publicity. Mining affairs are much to the fore these days in most of our newspapers and periodicals; but a large part of what is written, and read, is trash and most of the rest is propaganda in favour of stock-selling schemes and the like. From the point of view of the professional mining man, the larger part of the mining "news" now circulated is a joke.

The mining industry is no joking matter, and this continuous circulation of "news" that is a libel on the industry should be taken seriously by those interested in its progress. A serious responsibility rests upon each and every member of the mining and metallurgical fraternities, most of whom are at present content to sit back and smile at the gullibility of the average reader of newspapers and magazines. The same responsibility rests upon the various government departments concerned with the mining industry. It is the position of these latter that we shall examine briefly today.

Each of the provinces has a Department or Bureau devoted to its local mineral industry, and each of these is a centre, actual and potential, of information concerning the industry. The largest of these Departments, that of Ontario, is comparatively small, and its operations do not justify the organization of a special branch or service for sending out information and news. However, as all these Departments or Bureaus are small, they are conducted in a comparatively informal way, and on that account a good deal of information that would otherwise remain buried in their files commences on a career of useful existence in the public press. Nevertheless there is plenty of room left for extending this useful contact between provincial mining departments and the general public.

It is in the central departments in Ottawa, however, that the bulk of the information about Canada's mineral resources and their development is collected, and it is to Ottawa that we must turn for the bulk of our data and technical records. These are readily available in the form of annual and other periodical reports, memoirs, bulletins, and so forth, and in each department or branch the means is provided for giving all information available to those that inquire.

This provision does not, however, touch the problem to which we have reference in the present instance. A mere handful of our citizens will write for informa-

tion to Ottawa, whereas the larger part of them notice the paragraphs in the public press dealing, or purporting to deal, with mining.

Is it not feasible to effect a working alliance between the departments at Ottawa and the public press? Of course it is feasible. It has been done in the case of a number of departments, but not yet with the Department of Mines. The present Government realizes fully, as did its predecessor, the value of publicity in this connection, and three of the Departments,—Trade and Commerce, Immigration and Colonization, and Interior — have special branches for the purpose of spreading abroad authentic information. Until recently the Fisheries Department also had such a branch, and will have it again.

The Department of Mines should have a special publicity branch and we believe it could be had for the asking. A precedent has been set; the need is obvious; the expense would be trifling; the value returned would be a hundred-fold. Already the Department of the Interior, in its publication, "Natural Resources," issued monthly to the public press, includes articles dealing with our mineral resources. This should be amplified and systematised under a special officer of the Department of Mines.

A glance through this issue of the "Canadian Mining Journal" will show a number of paragraphs and short articles referring to the activities of the Bureau of Mines and the Geological Survey in Washington. These are selected from a dozen or more such press reports that come, each week, to our desk, generously made available by our neighbors to Canadian periodicals as well as to those in the United States. These press reports are valuable, both to the public and to the departments concerned. Their circulation prevents in large degree the garbled accounts that would otherwise be printed. There is a corps of over six hundred public employees in Washington specially charged with this work. In Ottawa we have three.

It is up to our Canadian miners and metallurgists, our Institute of Mining and Metallurgy, and others interested in the mining industry, to stimulate a request to the Government from the Department of Mines in Ottawa for a trained publicity officer, engaged at a salary adequate to ensure his proficiency. It is up to them also to back the Department of Mines in this request by every means at their command. The country, as well as the mining industry, needs this service.

### FIRE PREVENTION IN ROUYN DISTRICT

Fire will be a very serious menace in the gold district of northwestern Quebec during the coming season. None realize this better than the officers of the Department of Lands, Forests and Mines in Quebec, who are responsible to the people for the preservation and proper use of the forests, and the owners of the timber and pulpwood limits in the area affected. Both public and private property are threatened and must be protected.

Our correspondent for Quebec outlines today the measures that have been taken by the provincial government authorities for the prevention of forest fires in the Rouyn district next summer. These provisions seem to be eminently suitable to the case, as well as practicable. Their efficacy will depend mainly upon the manner in which they will be applied. Judging by the practical solicitude of the Quebec authorities for their forests as demonstrated in other instances, the enforcement of these preventive measures against fire will be strict and impartial. The Chief Forester for Quebec will have a big job on his hands next summer. One little forest fire will cost more than the upkeep of a whole staff of fire rangers.

The private companies owning timber and pulpwood limits in this area can, and no doubt will do much to aid the force of provincial fire rangers in protecting the forests from fire. These companies now use aeroplanes commonly, and a constant patrol over the areas congested with prospectors and miners will be a constant reminder of the personal responsibility that rests upon each man in the woods.

The key to the whole system of fire prevention is the fixing of personal responsibility. To this end the regulations of the Quebec government have been devised, and to this same end the efforts of their agents in the field will be directed. If every man entering the gold area, for whatever reason, is made fully to realize his responsibility, there will be few, if any forest fires. We hope that by this and other means the magnificent stand of pulpwood and the fine timber in this area may escape the havoc wrought by fire in most of the other mining districts in eastern Canada.

### CUTTING DOWN EXPENSES

In the natural course of things it cannot be long now before the Budget is "opened", as the phrase runs, in Parliament. While speculation as to its probable contents must necessarily be in the nature of guess-work, at the same time it would seem highly probable that these will not include any downward revision of general tariff duties. If we are right as to this, protests may be expected from some of the Progressives and from an occasional Liberal of pro-

nounced Free Trade proclivities, like Mr. A. R. McMaster, M.P. for Brome. But such protests, even if not merely formal, are likely, we imagine, to weigh little with the Government. For just now, when business conditions seem to be in process of definitely picking up, is no time for the introduction of radical tariff legislation with its inevitable accompaniment of business and commercial unsettlement.

It seems likely that those who advocate tariff reduction will have to content themselves with the commercial treaties with France and Italy as tending in the direction desired by those of their school of fiscal thought. In addition, they are likely to be somewhat appeased by the extension to Great Britain of the special rates accorded to France and Italy. But we confess we should be surprised if the Government were to lower the rates on British imports, except as just suggested, in order to make up for such diminution in the British preference as may be resultant from the negotiation of the treaties with France and Italy.

But, whatever the nature of the forthcoming Budget in such respects, it is sincerely to be hoped that it will not be a Budget providing for further increase in taxation. For if the trade of Canada is to make a recovery that can fairly be termed rapid, it is essential that there should be not an increase, but a reduction, in taxation. The present Finance Minister, during the past year, has more than once taken occasion to emphasize the necessity for the country to practise economy, and has himself made an earnest effort to reduce expenditures. But in spite of this the country has not succeeded in reducing its national debt. There are only two ways in which this can be done — either by increased taxation or by further reduction in expenditure. As we have just said, the adoption of the former alternative is bound to hinder the expansion of business. Accordingly, the Dominion Government must continue the lead it has given the country in the matter of undertaking retrenchments.

Before today we have called attention to the far too facile tendency of large sections of the public to regard colossal expenditures as unavoidable. This is true not only of large sections of the public, but also, unfortunately, of some Governmental authorities as well. And the time has come to call a halt to all this.

As a people, we unquestionably need to practise economy, both in public affairs and also individually, more than we are prone to do. Indeed, the equanimity with which large sections of the public are disposed to regard colossal expenditures probably has its rise in the individual extravagance which is all too prevalent in this country nowadays. There is great need among us in this country today for the placing of the right emphasis on the right things of life — for the putting of first things first. Addiction to extrava-

gance saps the foundations of good citizenship. For just as it is true that no person can practise thrift without being a better citizen, so is it equally the case that the will and the moral fibre are weakened by the placing of a false estimate on the pleasures that "easy spending" can bring. Thrift has a moral, as well as a material, value alike for the individual and for the nation. It is a character tonic for both. And, both individually and collectively, we need to lay that truth to heart if we are to cope successfully with the many and complex problems presented by the days in which we are living.

### POWER FOR THE GOLD MINES

The power situation in the north has changed with startling rapidity during the last few weeks. Five weeks ago, we pointed to the possibility of using Quebec power for Ontario gold mines; today that event seems fairly certain of consummation. While the Porcupine mines have been reduced to one-sixth of their normal power supply due to the recurrent period of low water, and while the provincial authorities of Ontario have continued to dilly-dally over the negotiations for power on the Abitibi River, the provincial authorities of Quebec have offered for sale the upper powers on the Quinze River.

Power from the Quinze River is, after all, the logical solution of the power problem for any and all the present and prospective mineral areas within a radius of a hundred miles or more. One of the reasons why a power company, or even a mining company itself, hesitates to develop a water-power for the use of mines is the comparatively short life of any but the extraordinary mine. A modern hydro-electric installation will exist usefully for scores of years. The average mine is worked out within ten or twelve years. Even the average mining camp has a life much less than that of a power development.

If the risk a power company takes when it depends for its custom upon mines is spread over a whole camp, it is much reduced. If its power serves a number of camps, the risk is still further lessened, especially if the camps be in different stages of development, one requiring an increasing amount of power during its youth while another's requirement it declining. When, in addition to a number of established and prospective mining camps, the potential market includes pulp and paper mills, saw mills, and a wide area where settlement is progressing rapidly, the attraction for the development of water-power is so much the greater. Such is the fortunate situation of the Quinze power.

Owing to this fortunate conjunction of circumstances, present and prospective, we can be sure that the gold mines about to be established in the eastern part of the gold belt will never suffer for lack of power as have those at Porcupine. The advantage to the new owners of the Quinze power and the owners

of the new mines will be mutual — each will help to develop and maintain the other. The 100-mile transmission line to Porcupine is well warranted by the proved value and comparative permanency of the mines there. It is probable that the Kirkland area, too, will require more power than is available from its present sources of supply before it is fully developed, and it is not far off the direct way from the Quinze River to Porcupine.

Meantime the mines of the Porcupine camp are confronted with the certainty of a shortage of power once more during the period of low water next winter. Small power developments now in progress will alleviate the situation somewhat, but they cannot make up the deficiency. It is improbable that the period of low water will be so long or that the flow will be so extremely attenuated as it has been this year; but still the loss of production due to shortage of power will cost the country millions of dollars. We can look to the Quinze power to right the case by the time the winter of 1924-1925 binds the waters of the north.

### ALBERTA COAL FOR TORONTO

The measures now in hand by the provincial government authorities in Toronto to test the feasibility of using Alberta coal there, are entirely admirable. They reflect in a very practical way the interest taken by the officers of the Ontario Department of Mines in the symposium on fuel supply at the Institute meetings in Montreal last month. No other authority is, we would judge, in so favourable a position to negotiate with the Canadian National Railways for suitable freight rates and for the provision of suitable rolling-stock for this long-distance haul.

It is hardly likely that any private company would be willing either to run the risk of financial loss on a shipment of coal from Alberta to Toronto, or to break their established connections with American producers. The government is fully justified in making the experiment, and the public can well afford to absorb any loss incurred in such a cause. The Canadian National Railways, too, have something to learn about the cost of hauling coal for such a distance, and their part of the experiment will be somewhat in the nature of research.

It is highly satisfactory to know that western fuel engineers, well accustomed to the use of Alberta coal, are already on hand to advise the prospective users in Toronto. This is a precaution whose neglect has wrecked many a similar attempt at progress in the past. From the evidence at present available, it appears that this first experimental shipment of coal from Alberta to the east will be made under the best possible auspices.

We are pleased to have Mr. Cole's definite assurance, in the letter on another page, that the Temiskaming Testing Laboratories at Cobalt have considered

carefully, and provided fairly for, the rights of private assayers in fixing the schedules of prices for assays. Mr. Cole does not mention contracts for assays in large numbers or other special cases, so we assume that these are covered in the general regulation. Any dissatisfaction with a public institution such as the Temiskaming Testing Laboratories can best be dispelled, if ill founded, by a public statement such as Mr. Cole's, and if well founded, it will be soonest mended by being brought to the light of day in public discussion.

Dr. H. C. Cooke's interim report on his geological survey of part of the new gold area in Quebec last summer will be published during the coming summer. Meantime he has prepared a short report giving the conclusions derived from his geological studies and some practical hints to prospectors, which appears in this issue of the "Journal". We are confident that the information thus made available by the Director of the Geological Survey at a time when many parties are preparing to work in the new gold field will be much appreciated by them. We shall look forward with interest to receiving the further information that will be made available when Dr. Cooke shall have completed further researches in the field during the coming season.

### THE PRESIDENT

Truly, a printer's error is sometimes worth while. If the "Canadian Mining Journal" had been unimpeachable in its proof-reading our poet would never have been inspired to the following verse, our artist would have lacked his present inspiration, and the President of our Institute would not have been immortalized thus by pencil and by brush:

#### The Wonder Child

John Dresser, who seems old enough to be  
 Father Confessor to yourself and me,  
 Was born (see Journal, March sixteenth and page  
 One ninety-nine in 'eighty-six. His age  
 When graduating from McGill was nine!  
 Great Guns! That's something wonderfully fine!  
 Precocious child! so lavishly endowed  
 With mental growth to others not allowed!  
 Say, Kid, I have no wish to treat you rough,  
 But how the dickens did you run the bluff?  
 I'm now aware, despite your light-blue eyes,  
 You are not preternaturally wise  
 As outwardly you seem. But, kiddo, say,  
 You're more than thirty-seven, ain't yuh, hey?

J. C. M.

To the Editor, "Canadian Mining Journal."

Sir: — In your article in the issue of March 16th on Mr. Dresser, our worthy president of the Institute, I do not think that you did the subject sufficient justice. In some ways your remarks are what is vulgarly called "slams". For instance you state that his record of

such work (geological) is voluminous. If it is voluminous and nothing else, surely nothing more cutting could be said about it.

Another point in which you failed to do him sufficient justice was in his remarkable achievement. It is stated that he was born in 1886, and graduated from McGill in 1893. I was so struck by this achievement that I got in touch with the McGill authorities and through Dr. Adams, who kindly introduced me to an official called the Archivist, I was able to get some interesting information. It appears that it has been a practise at McGill to make a portrait of any of their graduates who have shown extraordinary ability and keep them filed to see how they turn out in after life. The artist that I was able to persuade to undertake this, Mr...., was allowed to take a copy of this

portrait which I am enclosing for you to publish along with this letter. It is noticeable at once how well developed he seems to be mentally. His head dwarfs the body, and the blue eyes which are referred to in your article as the most striking feature, are well depicted by the artist. In fact they remind one of the old ballad: "With eyes so blue, and heart so true, that none with him compare."

I hope you will make good your delinquency by publishing this portrait and letter.

"Ardent Admirer of the President."

Official advice received privately in Montreal from the headquarters in New York of Continental Mines says that the contact has been cut in the Colonial shaft at Cobalt at 962 feet, and that it is "well mineralized." It was expected originally that the contact would be reached at 800 feet.

# THE MONTH

A CASUAL REVIEW

**The Uses of Adversity**—No mere warnings through the press would have sufficed to stir up the interest that Canadian governing bodies are now manifesting in the solution of our urgent fuel problem. Repeated shortages of coal, culminating in an incipient famine, have at long last opened the reluctant eyes of our legislators.

With this wakening has come a flood of talk, febrile talk and fallacious argument. Loquacious members of the Dominion Parliament have delivered themselves of multitudinous mouthings. Courses of action, incidentally sound, but **only** incidentally, have been urged as panaceas. As the question is complicated to a very high degree, and as it involves the closest study of the economics of mining, transportation, utilization, and labour, it is certainly not to be expected that the casual politician will be able either to diagnose the trouble or to prescribe the cure.

A general view of the situation indicates that relief will come in different ways in the East, Central, and West parts of Canada. The proposal to establish large by-product coking plants in large centres has much to recommend it. It is possible, however that low-temperature carbonizing plants may be better adapted for the double purpose of providing a domestic equivalent of anthracite and, at the same time, immediately saleable by-products. Quebec requires about 5,500,000 tons of coal annually; the Maritime Provinces and Newfoundland require not less than 2,500,000 tons. Since the output of New Brunswick is negligible, it is apparent that Nova Scotia's output will have to be very largely augmented if, in addition to taking care of the large demands of the railway and bunker trades and of its iron and steel plants, the total requirements of Eastern Canada are to be supplied.

The question of the extent to which Ontario can depend upon coal from Alberta has yet to be answered. The final answer must come from the executive heads of our national railways. As in Nova Scotia, so in the West, coking and low-temperature carbonizing will play a determinative part. It is to be regretted that we have heard nothing conclusively hopeful about the \$1,000,000 briquetting plant erected by the Dominion, Manitoba, and Saskatchewan Governments near Estevan, to treat the Saskatchewan lignites. The plant was erected at the urgent instance of the Research Council. The progress of the most recent experiments there has not yet been announced.

The most favorable survey shows no possibility of neglecting any longer, without suffering the direst consequences, the development of our huge and rich peat bogs. It will take ten years to make Canada self-supporting in fuel. Our coal mines cannot meet the nation's needs until they shall have been enlarged and re-organized. Our normal requirements amount to about 30,000,000 tons per annum, our output to half that total. In a few years our needs will have doubled. Every resource that is ours will have to be implemented with diligence and speed.

**Great Britain's Balance.**—The astounding resiliency of Great Britain's finances is comforting. The Govern-

ment's unexpected balance of £100,000,000 gives assurance of some easing of the terrific burden of taxes that citizens of Great Britain have been carrying. This, in turn, encourages us to hope that more overseas capital will be diverted to Canadian mining. Even now a fair stream of British money is coming over. The overseas investor's chances of fair treatment are incomparably better now than they have been in days past. They can be made still better if our newspapers will consent to take a stand against the slim promoter.

**Porcupine's Power.**—Comment on the quarrel between the Hollinger and the Northern Canada Power Company is not decorous, since the case is **sub judice**. Whatever the merits of the contestants' claims, the result is the same—the whole camp is paying the shot for somebody's stupidity—or cupidity. If investigation proves that the present grievous shortage could have been avoided, then somebody's crime should be fittingly punished.

**The Circle Widens.**—Last year, for the first time since official records have been kept, Quebec's metaliferous mines made no shipments. This, of course, was attributable to conditions that were temporary and that will pass. It is probable that gold production, on a respectable scale, will be begun as soon as the preliminary work of selection and development shall have been performed on a number of the genuinely promising properties east of the Ontario-Quebec boundary, and unmistakably in the same geologic province as are Porcupine and Kirkland Lake. Authentic information as to these deposits will not seep through for some weeks or months yet. It is eagerly awaited.

Meanwhile, English capital is being samely expended in a well-conceived effort to appraise the value of certain gold-bearing veins in the western part of Ontario that was once the cynosure of many eyes. Properties near Mine Centre will be given the benefit of modern attention. It is within bounds to say that if these properties were new discoveries they would attract more investors than—well—than they do. They are eminently deserving of painstaking investigation.

The Portland Canal region, which is essentially not a poor man's country, is coming into its own spectacularly. An intimate history of individual enterprises in this district would exhibit an astonishing reversal of professional opinion. The striking success of the Premier mine has had a repercussive effect. No doubt we are witnessing but the beginning of things in Northern British Columbia.

Taking it by and large, prospects for Canadian mining never seemed quite so cheering as they now appear. If we can mitigate the threatened frenzy of a "boom" then the position of the mining industry will have been greatly strengthened before the summer is over.

J. C. M.

The Italian production of sulphur fell from 313,400 tons in 1921 to 191,600 tons in 1922, thus reflecting the competition of cheap sulphur from Texas and Louisiana.

# THE QUEBEC GOLD FIELD

## GEOLOGICAL DEDUCTIONS, AND HINTS FOR PROSPECTORS

By H. C. COOKE

In accordance with its policy of keeping ahead or at least abreast of the prospector as far as possible, the Geological Survey sent a large party into Quebec in the spring of 1922, to commence the detailed mapping of the area east of Larder Lake. The work was undertaken because results obtained in Ontario in 1919 and 1920 had made it evident that the rock formations of the Kirkland and Larder districts extend eastward across the interprovincial boundary, and it was therefore anticipated that sooner or later prospecting would be carried into Quebec and ore deposits of economic importance discovered. The discoveries made in the latter part of the summer, and the consequent rush of prospectors to the area, have fulfilled these anticipations sooner than was expected.

### Area Mapped

The areas examined last summer, which are known as the Opasatica and Duparquet map areas, have been mapped in as great detail as time permitted. The new maps will be published on a scale of 1 mile to the inch, and will show not only the distribution of the various rock formations, but also the approximate size and shape of the various areas of outcrop, as nearly as these could be determined under the circumstances. Such a separation of rock areas from drift-covered areas is of value to the prospector, as showing where his operations can be most easily carried on. Particular attention was also paid to the mapping of the smaller bodies of acid intrusive rocks, since these appear to have had a genetic connection with the gold deposits.

Unfortunately the unusually early freeze-up last fall compelled the geological parties to leave the field without entirely completing the mapping of the areas assigned. The demand for information has been so great, however, that a report of the results obtained is being published in the Summary Report of the Geological Survey, accompanied by a preliminary map. It is hoped that these will be available about the end of May.

### The Temiskaming Series

The geological examination was productive of many interesting and valuable results, both economic and scientific. The latter predominate, it must be admitted, since the principal discovery that caused the rush into Rouyn township was made late in the fall when the geological party was leaving the field, and consequently the discovery was not examined by us; and since practically no reliable information concerning the tenor in gold of the ores in other deposits could be obtained that would enable them to be studied effectively. Many facts were gathered, however, encouraging to those who may be considering prospecting the district during the summer of 1923.

A belt of folded sedimentary rocks extends from near the Ontario-Quebec boundary eastward for nearly 100 miles, crossing the southern side of the area examined last summer. The sediments were termed

by M. E. Wilson, who examined the area over ten years ago, the Pontiac Series. When a somewhat similar series was later discovered in the Kirkland Lake district and there named the Temiskaming series, it became important to know what relationship existed between the sediments of the two areas, since if they were identical there might be a possibility that the gold would be duplicated in the Quebec area. Several years of work were required to answer this question definitely, and some years have been occupied in tracing eastward the Temiskaming of Teek township to the provincial boundary. It may now be definitely stated that the Pontiac series of Quebec is identical in age and relationship with the Temiskaming of the Kirkland and Larder Lake districts, although in Quebec the series has been much more strongly folded and metamorphosed than in Ontario. It is also more widespread and thicker in Quebec than in Ontario.

### The Syenite Porphyry

A rock of greater interest to the prospector is the syenite porphyry. In Teek township it forms good-sized sills in the Temiskaming sediments, and on account of its propinquity to the gold deposits is generally considered to have been the source of the ore-depositing solutions. In the Matachewan district it has been definitely proved to be the source of the gold ores. It is encouraging to note, therefore, that this rock has been found in considerable amount in the Opasatica district, and that, as in Ontario, it is closely associated with the principal gold deposits found up to date. Porphyry dikes are found on the property of the Lake Fortune Mining Company, and mineralization is most intense close to the dikes, dying away with increasing distance from them. I am also informed that there is a porphyry dike or dikes adjacent to the Powell vein, southeast of Rosebury lake.

The distribution of the porphyry appears to be rather peculiar. If a line be drawn on the map parallel to the Keewatin-Temiskaming contact, and about 5 miles north of it or thereabouts, the strip between this line and the contact will contain most of the porphyry dikes observed by us. It is possible that this distribution is due only to chance, and that further east the dikes will be found to have no particular concentration; or our observations may have been insufficient, as the greater part of the area is covered with a mantle of clay, which may hide many bodies of porphyry. With due regard therefore to these possibilities, it may be said that present indications suggest that the best area for prospecting is the band about 5 miles wide north of the Keewatin-Temiskaming contact.

### Two Intrusions of Porphyry

It was rather disappointing to find very few bodies of porphyry in the Temiskaming series within the area examined last summer. Only two were discovered, a large one between Olier and Renaud Lakes, and a smaller one on the east shore of Kekeko Lake near the north end. From a prospectors' standpoint it is important to note that both these sills occur in the Temiskaming conglomerate less than a mile from the Kee-

\* Published by permission of the Director, Geological Survey of Canada.

watin contact. The fact suggests the conclusion that the porphyry, during intrusion, found it easier to spread out along planes of bedding or schistosity in the Temiskaming, rather than to break across the bedding for any great distance, and consequently that it is not likely to be found in the upper beds, the schistose graywackes. The examination of the map of the Larder area tends to confirm this hypothesis, although the series is so much thinner there that porphyry might be expected almost anywhere. There is, however, an undoubted concentration of the porphyry toward the base of the series; the largest mass occurs on the contact between the Keewatin and Temiskaming series, and the others not far from the contact. In Teck township the series is still thinner than in Larder Lake, and the relationships are thus obscured. The conclusion may therefore be drawn with considerable assurance, that the area of profitable prospecting within the Temiskaming series will be found to be confined to the narrow belt of conglomerate along the northern contact, a belt rarely more than a mile in width.

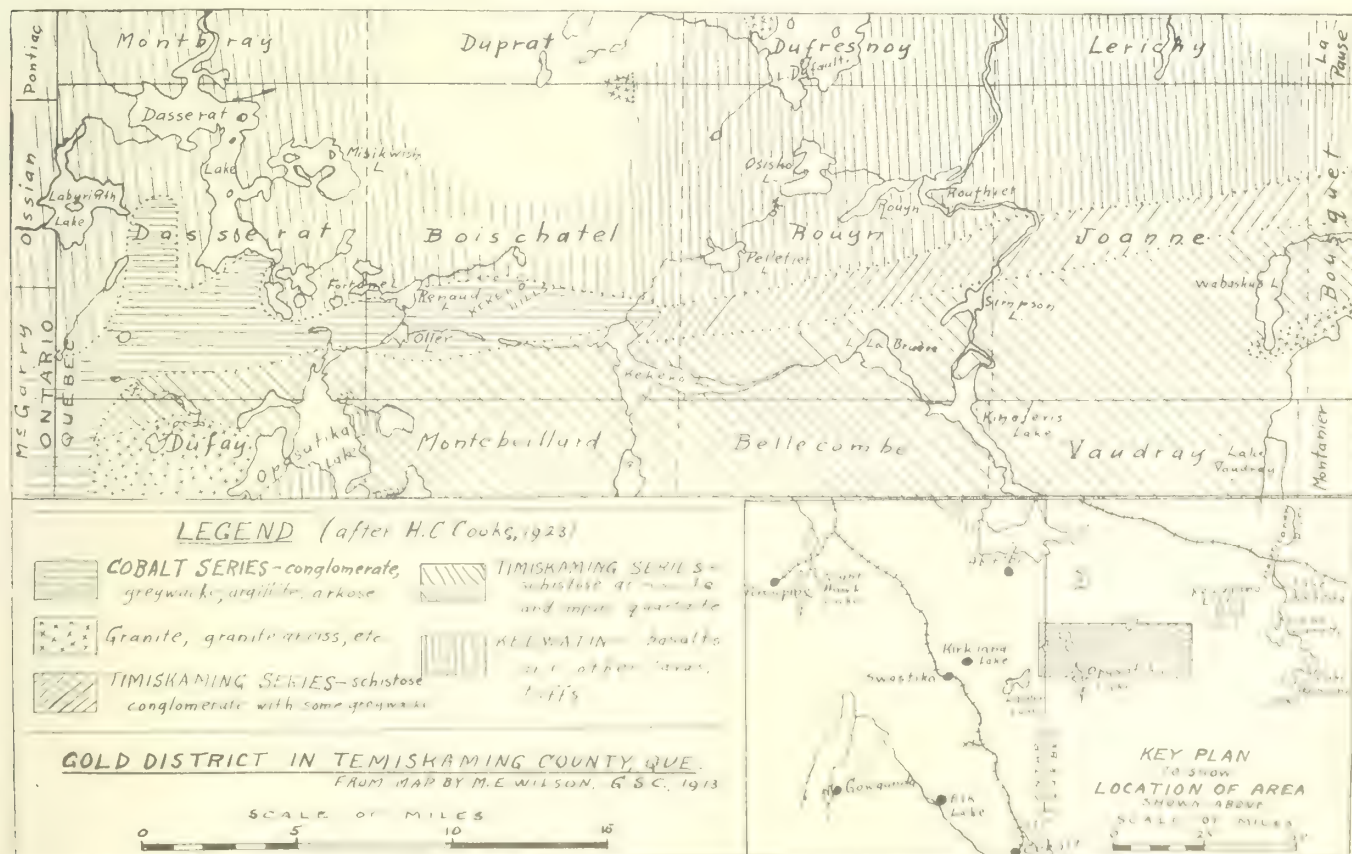

A third rock of possible economic significance is a dike rock termed syenite at Larder Lake. It is massive and reddish, composed largely of reddish feldspar and needles of hornblende. In places the rock has so little hornblende that it might be termed a felsite. Its texture in the hand specimen is for the most part fine-grained and even, though porphyritic in places; the microscope shows however that the porphyritic texture is characteristic, though the phenocrysts are usually so small as to escape recognition in the hand specimen. In places a good deal of pyrite is present, and in such cases also carries gold values, assaying \$2 or even

more per ton. It seems quite possible, therefore, that this rock also acted as a gold bringer, although proof of this has not yet been found. It is also possible that some place may be found where the rock itself is so heavily mineralized as to be itself an ore. The rock is thus well worth the attention of prospectors.

### Gold Occurs in Shear Zones

Burrows and Hopkins have called attention to the occurrence of gold deposits in belts of fracturing and shear at Kirkland Lake. Similar conditions prevail in Quebec. The Lake Fortune deposit occurs in a belt of highly schistose basalt that runs slightly north of east, and has clearly been formed by faulting. The reported discovery of Wright and Billings on Pelletier lake is in a shear zone of similar size and strike. The Horne discovery near Osisko lake is a replacement of highly shattered rhyolite, although the rhyolite appears to have been shattered by drag folding rather than by faulting.

It is thus evident that conditions at Kirkland Lake are duplicated by those in Quebec. In both places the ancient Keewatin basalts and other lavas and tuffs are overlain by a series of folded sediments, the Temiskaming series, and both are intruded by syenite porphyry. In both places the ore bodies are found in belts of shattering or shear in the neighborhood of masses of porphyry. It is evident, therefore, that the search for new ore bodies will best be carried on by looking first for belts of schist or shattered rock, and secondly for masses of porphyry. Belts of schist should be carefully followed up, and if they can be found to pass close to or into the bodies of porphyry,

(The above map, after M. E. Wilson's map sheet of 1913, has been shown by H. C. Cooke's surveys of 1922 to be essentially correct. The geological series have now been correlated with those to the westward in Ontario, and consequently Dr. Cooke's nomenclature is used above. With this exception the above map is the same as that used to illustrate our first description of the new gold field, in November last. — Ed.)

such a place should be carefully prospected, as it is particularly favorable for the occurrence of ore. It may be added that the most favorable type of schist band is one that has an average width of 6 to 30 feet in thickness. Schist bands are apt to be discontinuous and hard to trace, and even if ore were found in them it would have to be very rich to pay for working, and as for the large schist bands sometimes found, 100 to 400 feet in width, these seem to have afforded no large or abundant free ore-bearing solutions that have been passed through them, so that even where deposition took place, the great volume of rock is mixed with the vein materials and values are consequently low.

#### Heavy Cover of Clay

The principal difficulty to be encountered in the Quebec area is the heavy mantle of clay covering the greater part of the surface. The area has been a part of a great post-glacial lake, in which considerable thickness of clays and silts were laid down. Wilson reports thicknesses up to 25 feet along the National Trans-continental railway, and the thickness is probably some what greater in the Opasatica district. Consequently the only areas of exposed rock are the knobs and ridges that once formed islands and peninsulas in the ancient lake. Thus the area to be prospected is greatly reduced, and trenching is rendered somewhat more difficult. The clay also supports a dense growth of underbrush, almost tropical in its luxuriance, through which travel is slow and exhausting; over large areas the traveller must wade waist-deep through a sea of small shrubs, unable to see the ground or to avoid the numerous fallen logs, snags, and holes that beset his path. However, although the mantle of clay is baneful to the prospector it presents compensating advantages in other directions. In many places it supports a heavy growth of timber, a most valuable resource; and when cleared, as it undoubtedly will be in the next two or three decades, it will form as good farming land as any to be found in the north.

#### PLAN OF THE ROUYN GOLD AREA

Two mining engineers who are actively engaged in the development of the Rouyn gold area in north-western Quebec have compiled a plan of the area on a scale of a mile to the inch, white-prints of which can be obtained from E. B. Forrest, 18 Melrose Ave., Montreal. The information available from government reports, and maps forms the basis of the plan, to which has been added information from the recording office in Quebec and additional information obtained privately in examinations of the area. The plan shows, in addition to the principal topographic features, the geological contacts and the claims recorded, with names. It should prove very useful to those interested in the new

#### PROGRESS IN RESEARCH ON SPONGE IRON

Work has been conducted for some time past at the Seattle Station of the Bureau of Mines in the hope of developing a method by which sponge iron can be made by using low-grade coals and iron ore in a direct-fired rotary kiln. The sponge iron will be useful in the production of foundry iron and steel as also for the precipitation of copper from solutions resulting from leaching operations.

Tests will now be made in a small furnace treating about half a ton of ore per day. Attempts will be made to increase the rate of reduction of the iron oxides of the charge. Concentration studies will be made on the product with a view to obtaining a high grade sponge iron suitable for melting in an electric furnace or for use in precipitating copper from solution.

Melting this sponge to foundry iron involves its carburisation. Consequently the latter reaction has been studied on a laboratory scale and is to be continued on the commercial scale, using some of the local electric furnaces and foundry cupolas. A study of the mechanism of carburisation and of the causes of graphitisation will be conducted in the laboratory. After these studies have been completed, the conditions determined therein will be applied to the melting of sponge iron. — Bulletin of Cleveland Technical Institute.

#### LETTERS FROM READERS

To the Editor,  
Canadian Mining Journal,  
Sir,

I thank you for the editorial contained in your issue of March 30th, drawing attention to the activities of the Temiskaming, Testing Laboratories, and your favorable comments on the arrangements made by the Ontario Government for the buying of gold ores.

In your last paragraph however, your adverse criticism of the assaying department is based on false information and therefore calls for correction.

The sampling plant was originally built and operated by the firm of Campbell & Deyell, Limited. After operating successfully for a number of years, the sampling department became unremunerative and it was decided to close the plant. Mr. Campbell was making arrangements to carry on the assaying department on his own account, when the Government purchased the plant, one of the conditions being that the assaying department should be included. You will therefore see that no new competitor was introduced, but the Government simply carried on a business already in existence. The government however does not stress this part of the work of the Laboratories but carries it on as a necessary adjunct to its other operations of sampling and ore-testing. Moreover, in order to avoid any, accusation of unfair competition with customs assayers, the government raised the prices of the private company 50 per cent and on this basis the business has been run. In the cases of two Cobalt companies, (silver) the Government made specially low rates carrying on old contracts entered into by the former company, but neither of these contracts is now operating. If our clients are willing to pay our higher prices, it would be natural to infer that they consider the service given worth the higher expenditure.

Copies of our schedules are enclosed herewith.  
Cobalt, Ont.,

Arthur A. Cole  
Manager.

Temiskaming Testing Laboratories.

The Alaska Railway the first railway to be built been completed recently by the opening of the Tanana and operated by the United States government, has bridge.

## Making Economic Treason More Difficult

By ALEXANDER GRAY

Statutory antiseptics for speculative improvidence, unwisdom and inexperience have been prescribed by an Ottawa Senator. Thereupon divers and sundry colleagues indulged in one of those oratorical dress rehearsals that encumber the record and convince materialists that "the problems of the world would be settled in a week if we were not so busy solving them, that we have no time left for work." Rude mirth among the gallery occupants — the cynics — and applause from those that crave a code that will rectify intellectual debility, leave matters precisely as they were.

Ottawa thinks of making it an indictable offence for any person to solicit the sale of stock unless the solicitation is authorized in writing by Dominion or Provincial authorities. But it also exempts those who avail themselves of advertisements or circulars, which would weaken the legislation as proposed. Tweedledee and Tweedledum being confusedly juxtaposed, Ottawa's dilemma is no different from that of other administrative, legislative and judicial fountains of wisdom and justice. How to promote sanity among the populace and thwart those who prey upon the credulity of the imprudent, is a problem of increasing moment.

Many are anxious to do something in order that Ponzi, Piggly Wiggly, Stutz, Get-Away-With-It stunts shall be less frequent.

### Opinions of "Wall Street"

"Stealing money in Wall Street seems to be as easy as taking candy from a kid," said Judge Rosalsky, of New York, in passing judgment on crooked bucket shop principals. "Brokers who swindle their patrons and come before me need expect no leniency."

"As long as I live," declared the President of "Piggly Wiggly", who found his company's stock oversold, "I will not be president of any company again that has its stock traded in on the New York Stock Exchange, where the gambler and the speculator have such free reign to ply their trade."

There we have the juridical and lay view of speculative conditions. It remains to be demonstrated whether the graven images will be shattered. Indignant jurists, irate "Piggly Wiggles", the befuddled public and official custodians of the popular conscience, all blame "Wall Street," reckless promoters and speculators, bucket-shop burglars and their ilk, who make it difficult to discriminate between those who have honorable purposes and those who ply their thievery until caught.

According to Judge Rosalsky and the "Piggly Wiggly" president, it is "Wall Street" and Stock Exchanges that are culpable, from the requirement that in commodity exchanges are excluded, for the time being. The Curb Market, being an adjunct to "Wall Street," is included in the arraignment. The whole financial district is an Augean stable, Alsatia up to date. Instead of mines and mining script being pilloried as plundering beyond endurance, here we see the most decisive factors in fiscal affairs so enmeshed in kna-

very that experts in rascality must chuckle. To have "Wall Street" (which embraces Broad Street, New Street, Broadway, William Street and Exchange Place, not forgetting Nassau Street) within the application of Judge Rosalsky's generalization and made to appear as a haunt or lair, is nectar for the nefarious traffickers. Soap box orators and the Fagin element have the word of the Law and the Lawless that nothing good can come out of Wall Street.

By the same token, the "Thieves Kitchen" in Throgmorton Street was aptly named; the Bourse and Boersen are the abodes of malefactors; each and every Exchange — Stock, Cotton, Coffee, Grain, wherever securities or commodities are traded in — is deserving of maledictions and drastic regulation. As for so-called Mining Exchanges, — so utterly utter are they according to those who know nothing about them or who have it that mining of any sort has more percentages against the player than any game of chance — they are so many plague spots deserving of quarantine.

### Exchanges not Solely Culpable

Gamblers have their ups and downs (mostly the latter) in Wall Street, or wherever the cards are dealt from the top and the bottom. If the "pictures" come to the liking of the players, well and good. The marble and the whirling wheel are where you can see your money go; so much cannot be said of innumerable devices whereby Barnum's psychology is proved. A billion-a-year put into fraudulent schemes and worthless securities, however, cannot be laid on the doorstep of "Wall Street" or its synonymous organization in any country, so long as fools and their money are so easily parted and paternalistic legislation is ineffectual against predilections for speculation. "Blue Sky" prescriptions are unavailing, except as admonitions. What cannot be accomplished in the open will be surreptitiously achieved.

The inconsistency of Ottawa in proposing that no securities be sold without authority from Dominion or Provincial authorities, but that circularizing and advertising go unmolested, evokes ridicule. Predatory "brokers" have shown how they can reach the isolated, regardless of "Blue Sky" inhibitions. If reputable brokers (who constitute the infinitely greater number of their class in every great community) would join with investment bankers in a campaign of education, and if advertising departments were more scrupulous, ignorance no longer would be an excuse for parting with cash and dissipating credit that could be utilized in safer enterprises. Discussing this phase and the general urge for remedial legislation and stricter adherence to the verities the "New York Sun" recently had this to say editorially:

"Neither paternal legislation nor educational campaigns will offer complete panaceas. Paternal legislation presupposes ignorance of the majority of men in money matters; education is more promising, in that it gets at the roots of the trouble. But neither takes into account the man who does not want to be pro-

invest or convinced, the man who is actuated by greed, by the desire to get something for nothing, by the eagerness to get fifteen per cent. on his money. It is this man, multiplied, who contributes the most of the billion dollars. He will squirm through nearly any protection, resist nearly any educational campaign, when greed has him by the throat."

### Self-Regulation, not Legislation Required

Replying to the same issues, the "Montreal Gazette" contended that deliberate fraud now is punishable by law, and no law can be drafted to ensure a company against errors of management, mistakes by officials or failures to appropriate changes in the currents of business: "The real protection of the public against fraudulent or foolish investments must lie in the application of common sense to the consideration of the proposals made to its individual members by whoever appears as a vendor of securities or merchandise, lands or anything else of value. Laws cannot be made to secure any such simple protection. The public cannot be taught to be cautious where caution is most needed, not even by experience."

Advocating the improvement of existing laws, and citing the gruelling experiences with "L. R. Steel", against which the public had been warned repeatedly, The Toronto "Globe" adhered to the idea of excusing errors of estimation while imposing further safeguards. It said: "Take the case of gold or oil stock. There may be deliberate fraud. The gold mine may be salted; the supposed oil well may be an ordinary well of water into which kerosene has been poured. On the other hand, the seller himself may be deceived. What he supposed to be a rich vein of gold may be a pocket or a thin vein which peters out; a genuine oil well may be exhausted or its contents drawn off by some rival pumping in the neighborhood. In regard to a manufacturing or trading concern the business conditions may be misjudged. What the buyer has to remember is that there is an element of risk and speculation in all these things, and that the higher the dividend held out as an attraction the greater the risk. Either the buyer must himself be a shrewd business man or he must have confidence in the character of the seller if he is to be reasonably safe..."

"This does not mean that the law is as effective as it might be or that no improvement can be made. There might be stronger provision against fraud or against the holding out of prospects that cannot possibly be realized. The Regina Leader says that many Saskatchewan people might have lost money in Steel stock if it had not been for the firmness with which the officials of the Saskatchewan Government Board refused to countenance any sale of the stock in that Province. Three such attempts were made in vain."

### Well-Conducted Stock Exchanges a Necessity

Out of this discussion the conclusion is possible that, once more, corrective or prohibitive laws are applicable only insofar as they are enforced or enforceable. "Wall Street" is no more culpable than is Washington for the travesty of the Volstead Act. Barnum was right; yet there are those by legions who resent encroachment upon their liberty of thought and action in matters speculative, and other legions who know it all or blindly follow "tips". How to keep money calls for even better judgment than what to invest or speculate in. It is a delusion that this generation as

a whole is any more discreet or sapient than its predecessors, when it comes to being "touted". There are more "touts", more "dips", more "dippies", if the vernacular of the long-fingered and second-storey fraternities be permissible.

To circumvent the iniquities it may be effectual propaganda to denounce certain Canadian stock brokers as "ravening wolves" but it is subversive of exchanges as genuine and indispensable institutions. Were it not for the scrutiny of stock exchanges there would be lower standardization and chaotic valuations, and the covert or aggressive iconoclast and booster would ply his profession without molestation.

Stock Exchanges in the main are constructive. Patrons thereof are apt to overdo things. Brokers belonging to such exchanges cannot designedly destroy their following, becoming "ravening wolves", as the malevolent allege, simply because crops of customers cannot be raised often enough, if for no other reason. Nor can it be reckoned that "the unbeatable game" works one way, on behalf of manipulators. Lawrence Livingston, acknowledged to be the Wizard of Wall Street at this writing, stated the forceful truth, thus: "I can assure you the mere mechanics of deception is of little value. The difference between stock market manipulation and the over-the-counter sale of stocks and bonds is the character of the clientele rather than in the character of the appeal."

### Masters of Speculation Sometimes Fail

The daily speculator who ignores or does not discern the dangers of over-trading, invariably quarrels with his broker, who has his more conservative clientele and his own credit to protect. Even the wisest do not foresee the inevitable. When Anthony Brady died, his estate was larger than that of Morgan's. The Brady trustees, notwithstanding their familiarity with its affairs, did not get rid of all their Brooklyn Rapid Transit shares. They failed to realize that a receivership was impending. Others "on the inside" lost heavily. From this the deduction is drawn that the shrewdest of capitalists and speculators frequently misread their own situations, with trouble at hand. No one will dispute that H. H. Rogers was a master manipulator and magnate. In 1907 he was complacent in the retention of copper stocks, unmindful of the collapse in earning and values that came on the crest of unprecedented prosperity. Further back, the President of the Union Pacific admitted he was overloaded with his own stock in the debacle of 1893. Over-reaching "bulls" betimes are bagged by the "bears". Heinze was a genius of speculation — and got "the count." Gates was mangled, but managed to amass a fortune. We saw Durant at the Mercy Seat. Morgan over-estimated New Haven. Ryan "cornered" Stutz, and "Wall Street" put him in Chancery. Schwab was saved by Carnegie. Livermore has awakened to find he is not infallible. Supermen are not insuperable. Carnegie was vilified for "playing safe."

### Internal Discipline Required

When all is said and done and vituperation has run its course, speculators are essentially of mamillary tendency. "Blue Sky" atmospheres alone will not correct organic or economic ills. The theaters of finance must function if world movements are to be uninterrupted. While mere money-making is not regarded as the most admirable of human accomplishments, it is inadmissible that business could be conducted without

exchanges, which stabilize values even in spite of manipulations. "Sound manipulation", says Lawrence Livingston, "must be based on sound trading principles." What economists and metaphysicians who are endeavoring to minimize speculative wrong-doing will have to bring about is what is described by a recent writer as the "back-to-the-cerebellum movement", the "mastery of the submerged, conscious mind." Mid-Victorian statutory regulations are not going to alter prevalent predilections for risks in the race for a share of the wealth of nations. The glories and glammers of the age are apt to unsettle the finite mind.

Well-wishers of stock exchanges of late have noted the tendency of well-intentioned and reactionary persons to make the language of Emma Goldman, Jim Larkin and Trotsky tame by comparison. Radicals at Westminster and Washington, bloes of one kind or another, have joined in the crusade; and the worst of it is, there is some justification for the outcry against "outside" brokers in particular and against professional manipulators who do the bidding of the higher-ups.

The truth is, there is need of strict discipline within the exchanges and more sanity among large and small speculators. Abuse and the indiscriminate slanging of brokers gets nowhere when the public is eager to fling discretion to the four winds.

"He either fears his fate too much  
Or his deserts are small.  
That dares not put it to the touch,  
To gain or lose it all."

That is intoxicating to those who cannot carry it. Ontario and its Attorney General will have a strenuous time when script editions are "authorized."

### MAGNESITE AND ELECTRIC POWER

Canada's production of magnesite has dropped to zero. There may be an opportunity for its revival in the fact that a basic refractory of the highest quality is now made by sintering magnesite in the electric furnace. This process is now in operation by the Carborundum Company, with promising results. The availability of cheap electric power as well as raw magnesite might stimulate the use of this process in Canada.

### TO UTILIZE ENORMOUS WASTE

Utilization of immense waste from lumber by carbonizing and pressing into fuel briquettes equal in value almost to anthracite has been accomplished in saw-mills in the Pacific Northwest, the National Lumber Manufacturers' Association claims. The process, besides supplying the charcoal briquettes, gives by-products such as tar oil, fuel gas, acetone and alcohol. It is said it will make comparatively cheap fuel available to metallurgical and other industries as well as to homes. It will also facilitate the clearing of cutover waste left by the lumber cutters. The new carbonizing and briquetting process has been developed in a plant at Centralia, Washington, and it is planned to erect ten commercial briquetting mills from Vancouver, B.C., to Marshfield, Ore. It is pointed out that the result if applied to the entire lumber output of the United States would be nearly ten million tons of the briquettes annually.

### THE CASE FOR REVISION OF THE COAL MINING LAW IN NOVA SCOTIA.

#### No Revision Since 1877

In 1908 Mr. T. E. Forster was brought over from England to advise on under-sea mining. After making a careful examination of the submarine areas of Cape Breton, he submitted a report. In it he points out that the provisions of the Nova Scotia Mines Act were drawn up about the year 1877 by Mr. H. S. Poole, then Inspector of Mines. They appear to have remained unaltered (except for one variation on a matter of detail) since that time. After dealing with the different clauses of the Act, and after stating that the only case in which definite regulations for the working of under-sea coal (similar to some extent to those in force in Nova Scotia) have been established is New South Wales, he goes on to say that special conditions occurring in that coal field differ greatly from those of Nova Scotia and for that reason he considers that these regulations generally cannot be taken as forming a guide to those that would seem to be necessary in the case of the Nova Scotia fields.

Referring to the "panel system" of mining in Nova Scotia, he says, "I do not think that any importance can be attached to this method of working, but I consider that it is better to rely on the pillars left for the support of the roof being properly proportioned, with a fair margin of safety, and a careful restriction of the width of the working places and disposition of the same. I am of the opinion, therefore that no advantage can be obtained by the retention or these provisions and that their elimination from the regulations would not lessen the security of the mines, while it would, on the other hand lead to a saving of coal and give improved facilities for working. I am strongly of the opinion that the conduct of under-sea workings cannot, generally speaking, be advantageously provided for by hard and fast rules, and that a careful consideration of the circumstances of each case guided by experience gained in the gradual development of operations, is the proper system to be pursued in such cases.

After working the under-sea areas for the past fifteen years or more, the Cape Breton coal companies have reached the same conclusion as Mr. Forster. In the meantime great expenditure has been made in opening up large districts, taking some coal out, but leaving the great bulk of it behind. The openings that had to be made to win this coal are sufficient to destroy the mine in a very short time should any inrush of water occur.

They afford no safety, but being there by law for safety, are merely a delusion to the mine officials and the miners depending on them for protection of life and property. One opening (and there must always be more than one where haulage is carried on) would admit enough water, especially from the sea, to fill up any colliery. But for ventilation purposes there must be an intake and return airway, feeding and fed by the many other places in a working district. The old provisions of the Mines Act have created a menace to ventilation and have therefore added a danger more constant than that of sea water and equally threatening to life.

No attempt has been made to revise the provisions of the Mines Regulation Act since 1877. Surely that is making haste slowly. The time is now opportune for a revision, which will place under-sea mining in Nova Scotia on a practical and economic basis. — J. M.

### A NEW HINTERLAND

The little-known part of northern Canada crossed by the new Manitoba-Ontario boundary line is described in the current issue of "Natural Resources", the publicity organ of the Department of the Interior, Ottawa, from which the following is extracted:

Every extension of lines of survey and communication into the unknown or little known areas of Canada brings to light resources the existence of which had previously only been conjectured. This was the case in the course of the work done in 1921-22 in determining and marking the Manitoba-Ontario boundary northward from the Winnipeg river.

While the primary object of the survey was to mark the boundary, the importance of collecting topographical and other information, which could very conveniently be done at the time was not lost sight of and special divisions of levellers, geologists, and topographers were attached to the survey party. The length of the line surveyed is about 180 miles. Through this district, also, over 1,100 miles of shore line of lakes and rivers have been mapped, the location and character of all timber along the line has been noted, the adjacent country has been examined geologically, and the elevation above sea level of all points along it has been determined.

Though the extent of this information is in itself small when the size of the area is considered, it furnishes a base from which timber, geological, water-power, and topographical exploration may be economically extended.

While very slight information is yet available regarding the topography or resources of Patricia or the area north of it, the information at hand indicates that a large part of this district is naturally timbered country. The same geological formations that have proven a valuable asset in both the country to the south and east and in the Pas district to the west are to be found here; and water-powers capable of being harnessed into immense developments are known to occur throughout. The entire district is filled with lakes, rivers, and topographical features that are not even suggested on present maps.

In view of the present lack of information in regard to these areas, is it too much to suppose, when full information is obtained, that their resources will occupy a place in keeping with those of the older part of northern Ontario? A reference to these latter resources reveals their extent and range.

The per capita export of wood products in Canada, including pulp and paper, is among the greatest in the world and ranks next in our Dominion to the export of grain. The pulp and paper industry is now carried on through nearly all that part of northern Ontario served by the three transcontinental railway lines that link the grain-producing prairies of the West to Eastern Canada, and at the present time is reaching out into what are now the more inaccessible parts of this area. Two of the pulp mills in operation are among the largest in America.

Another resource—the mineral—has recently come into prominence and has become an integral factor in the development that has already taken place in parts of northern Ontario. The annual silver production and gold production at Cobalt, Porcupine, and surrounding districts is in each case roughly about seven per cent of the world's output. The greatest nickel deposits known are in northern Ontario. In addition there are important copper and iron deposits.

This area possesses, as well, a fertile extent of agricultural land estimated at 16,000,000 acres. On the Winnipeg river, near the boundary between the provinces of Ontario and Manitoba, two immense water-power developments are now in operation and a third is under construction. The fur trade in the vicinity of the Ontario-Manitoba boundary is one of the most important of any of our fur-producing districts.

Thus considering the resources already known and those fore-shadowed, it is seen what a heritage Canadians have in this unexploited and practically unexplored hinterland.

### VOLATILIZATION OF COPPER AND LEAD

Copper volatilizes readily in the chloride volatilization process states the Bureau of Mines, Washington, in Bulletin 211, recently issued. Copper forms with chloride two salts—cuprous chloride and cupric chloride. Cuprous chloride, is the more stable at elevated temperatures. The chlorides, even at temperatures below redness, are volatile. When heated the cupric salt changes to cuprous, and volatilizes as cuprous salt. In an atmosphere of hydrochloric acid, however, the fumes of cuprous chloride may be partly raised to the cupric form, hence collected fumes are usually mixtures of the two chlorides. Oxychlorides of copper may take some part in these changes but, according to tests on collected copper chloride fumes, not an important one.

The reactions between sodium or calcium chloride and the oxidized ores of copper are rapid at moderate temperatures; as extremes of neither time nor temperature are required, the volatilization process for copper from ores is desirable commercially. The percentage of copper may take some part in these changes but acchloride fume to metal by fusing it with lime and coke affords a simple method of treatment.

The presence of some sulphur in copper ores probably helps rather than hinders the chloridizing reactions. On the other hand, if the proportion of sulphide is large, copper sulphate occurs in the fume; when reduced, such fume gives considerable copper matte along with metallic copper. Little iron is volatilized, and the matte occurring with the metal runs high in copper.

Lead is usually the most easily volatilized of all the metals thus far investigated. Lead has been present in nearly every kind of ore treated by volatilization at the Intermountain station, and in nearly every test its recovery or extraction has been higher than that of any other mineral constituent.

### NEW GAS MASK

A "universal gas mask" has been developed by the United States Bureau of Mines, and is described in Technical Paper 300, obtainable on request. The new mask is said to combine convenience and efficiency to a marked degree, and can be used in any air contaminated with small proportions of noxious gases, but with sufficient oxygen for respiration.

### ZINC PRODUCTION OF THE UNITED STATES IN 1922

During 1922 there was produced 352,786 tons of zinc, at a selling price of 5.6 to 6.0 cents a pound, against 200,500 tons worth 4.9 to 5.6 cents a pound in 1921 and 463,377 tons worth 8.0 to 8.4 cents a pound in 1920. Electrolytic zinc accounted for 55,334 tons.

## CANADA'S RESOURCES OF TITANIUM

Titanium white, a new pigment of which the essential constituent is titanium dioxide, is now being made from the mineral ilmenite. This pigment, which is said to possess certain very desirable properties in a higher degree than any other similar material now on the market, is being produced commercially both in Norway and in the United States. It is sold under various trade names, such as kronos brand titanium white (Norwegian) and titanox (U. S.)

A report on Titanium, by A. H. A. Robinson, recently published by the Mines Branch, Department of Mines, Ottawa, discusses the manufacture, properties, and uses of this new pigment as well as those of other useful titanium compounds, and describes in some detail the occurrence in Canada of large unexploited deposits of titanium ores that may in the future become of considerable industrial importance.

In the Province of Quebec, for instance, within 70 miles of Montreal and also within 90 miles of Quebec city, there are large bodies of ilmenite that are readily accessible, that can be cheaply mined, and that show every evidence of being capable of furnishing an output large enough to meet any probable demands for many years to come. In the past, occasional small shipments have been made from them for export to the United States — to be used in the manufacture of ferrotitanium; but the benefits to be derived from any possible export trade in the raw mineral would be small in comparison with those that would accrue from the establishment of a local titanium industry, such as the manufacture of titanium white, for which the conditions seem eminently favourable since the deposits are within easy distance of abundant supplies of hydro-electric energy and markets for finished products. If it is possible to make a commercial success of titanium industries in Norway and in the United States, there is no obvious reason why such an industry could not also be made a success in eastern Canada.

This report on titanium, which comprises 119 pages of text, may be obtained by application to the Director, Mines Branch, Department of Mines, Ottawa.

## GAS AND PETROLEUM IN WESTERN CANADA

During the year 1922 boring operations for the discovery of oil and gas were conducted in different districts in the province of Alberta, in the North West Territories, the Railway Belt of British Columbia and some boring was done in the provinces of Saskatchewan and Manitoba.

Up to the end of the last calendar year, there had been about 230,000 feet of drilling done in Alberta alone. The results have been the discovery and development of one of the great gas fields of the world, the output of which amounts to 180,000,000 cubic feet per day, and is used for domestic and industrial purposes in many of the towns and cities of southern Alberta, particularly in the cities of Medicine Hat and Calgary.

In addition to the gas wells there are six wells producing oil in Alberta, all situated in the southern Alberta foothills area, and one well in the North West Territories. The output from the wells in southern Alberta is not large, but it has been found to be profitable to operate them.

In the provinces of Manitoba and Saskatchewan

and in the Fraser River valley in the province of British Columbia, where some prospecting was carried on, no producing well has yet been developed.

During the year under review, a number of oil wells in the state of Montana, near the International Boundary Line, were "brought in." As result of the success in obtaining oil in Montana, seven different companies commenced boring operations on the Canadian side of the boundary line, but only one has as yet reached any considerable depth, and in this well there are indications of oil and gas, but a producing well has not been obtained.

During the winter months operations ceased in most instances, but it is expected that with the advent of spring, and the resumption of work, some of the uncompleted wells will become producers, and that a number of new wells will be commenced. — "Natural Resources."

## BOOK REVIEWS

SILVER (1913-1919). — Imperial Mineral Resources Bureau — Imperial House, Kingsway, London, W.C. 2, and The British Commonwealth Publishers, Ltd., Montreal, Toronto, Ottawa and Winnipeg — 218 pages — 4s. 3½d. post free.

Though nominally concerned with the six years denoted in the title, this report contains more recent information as well. After reviewing the position of silver in the world's commerce it gives data concerning the world's production and reviews the sources of the metal throughout the world, with attention principally to the British Empire.

In the introduction it is noted that "the world's output of silver is now so largely a by-product in the treatment of argentiferous copper and lead ores that the supply of the precious metal, and consequently its price, may vary widely with the production of such ores."

Canada is the chief producer of silver in the Empire at present, though the annual amount declined from 32 million ounces in 1913 to 13 million ounces in 1921. Australia is second in importance, with 15 million ounces in 1913 and 8 million in 1921, principally from the lead-silver-zinc ore of Broken Hill. India has risen from 125,000 ounces in 1913 to 4 million ounces in 1921, due principally to the rise of the Bawdwin silver-lead mine in Burma.

In Europe silver is won only from lead ores, the largest producer being Germany, with 6 million ounces in 1913 and 3½ million in 1920. Next comes Spain, with 4 million ounces in 1913 and 2½ million in 1921. Africa has no important producers of silver at present and in Asia, Japan leads with 5 to 7 million ounces a year, mainly from ores of lead and copper. In South America, Peru leads, with about 10 million ounces a year, mainly from copper ores while Bolivia produces about 2½ million ounces annually and Chile had reached the same amount in 1920.

The principal sources of the world's silver are in Mexico and the United States. Until recently Mexico produced normally about 70 million ounces a year. For most of the last ten years revolutions cut down the output, but in 1921 it had risen again to 64 million ounces. Formerly precious metal ores were the chief source of silver, but recently base metal ores have become very important.

The United States production of silver is about

equal to that of Mexico, varying from 75 million ounces in 1915 to 53 million in 1921. It is derived from siliceous silver ores, copper ores, and lead ores roughly in equal proportions, that from zinc ores and lead-zinc ores providing only a minor amount.

A bibliography of sixteen pages arranged by countries, concludes the volume.

**PROCEEDINGS OF THE NATIONAL SAFETY COUNCIL.** — Eleventh Annual Safety Congress, Detroit 1922. — National Safety Council, 168 North Michigan Ave., Chicago—1074 pages.

This compendious volume will prove a veritable fount of information to those especially interested in safety work. The Mining Section comprises over 100 pages, containing general discussion, sixteen papers and the discussion on them. The papers include mine hygiene, transport below and above ground, prevention and fighting of mine fires, and safety training and propaganda.

**MINING MANUAL AND MINING YEAR BOOK.** 1923. — by Walter R. Skinner — 15, Dowgate Hill, Cannon Street London, E. C. 4. — 824 pages — price 21s. 6d. post free.

Owing to the interest now being taken in the mining industry this reference work, which is the only annual book published dealing with mining and kindred companies operating in all parts of the world, appears at an opportune moment. This year's issue contains full particulars of 1,350 mining companies, gold, diamond, silver, copper, tin, iron and coal; also exploration and mining investment companies arranged in alphabetical order. The particulars given of each company include the directors and other officials, date of establishment, seat of operations, description of the property, with the purchase consideration, plant erected or in course of erection, present working results, ore reserves, details of capital, calls, dividends paid, and the financial position as disclosed by the latest accounts, highest and lowest prices of the shares for the last three years, also latest price. Lists are also given of the officials connected with the companies and comprise 3,700 directors and 900 mining and consulting engineers, their addresses and the names of the companies with which they are connected. Other useful features of the book are the supplementary index of 2,260 private and dormant companies and those that have ceased to be of public or market interest; crushing tables and outputs from the principal gold mines, showing tons treated monthly, results obtained, and yield per ton; also a dictionary of mining terms.

Mr. Skinner's annual volume, now in its thirty-seventh year, is indispensable to the mining man whose interest takes him beyond his own mine, as well as to the hosts of investors and others to whom mining is a live issue.

**A. S. T. M. — INDEX, 1913-1920** — American Society for Testing Materials, 1315 Spruce Street, Philadelphia, Pa. — 189 pages — price, cloth \$2.50; half-leather, \$3.50.

The proceedings of this important engineering society are now so bulky, and reference to them is re-

quired so constantly by many engineers, that the present index will find wide-spread use. There is an author index in addition to the subject index, and a list of key words comprising eleven pages to aid in using the index.

### NEW USES OF NICKEL

The current number of "Industrial and Engineering Chemistry" contains an article by A. J. Wadhams, manager of Development and Research for the International Nickel Co., giving some of the results of his work and that of other researchers on nickel. Since losing such a large fraction of their former market due to the reduction of battle-ship building, new and extended industrial uses have been sought. Chief among the new developments is a nickel-bearing type of stainless steel, containing 20 to 40 per cent nickel, 6 to 12 per cent chromium and 0.25 to 2 per cent silicon. The mechanical properties are good, as for example a rolled sample giving:

|                     |                          |
|---------------------|--------------------------|
| Tensile strength    | 100,000 lbs. per sq. in. |
| Yield point         | 60,000 lbs. per sq. in.  |
| Elongation in 2 in. | 20 percent.              |
| Reduction of area   | 50 percent.              |

These steels can be readily machined and fabricated. Seamless nickel tubes are now available, consequent upon the production of malleable nickel, amenable to the process of piercing and drawing by which seamless tubes of copper and steel are made.

Nickel added to cast iron in amount from 2 to 4 per cent increases its usefulness markedly, and a number of foundries are experimenting with its use.

Research has indicated that a new nickel-silicon steel has unusual properties of hardness and toughness, and that it is likely to be of commercial importance.

### ROCK DRILL STEEL

"A Handbook of Rock Drill Steel—its Selection, Heating, Forging and Tempering", is the title of a neat 80-page booklet of pocket size just issued by the Sullivan Machinery Company, as circular No. 72-G. Besides being an instruction book for the use and care of Sullivan drill steel sharpeners and drill steel furnaces and accessories, it includes instructions for the proper selection and treatment of drill steel, practical specifications for drill steel, and comprehensive data for the lay-out and construction of an ideal steel-sharpening shop. Among the devices available as aids in this ideal shop are a signal pyrometer, to notify the smith when his heating furnace is becoming too hot, and a simple magnetic indicator to indicate the proper temperature for plunging the hot steel. This latter is simply a magnet suspended in a brass case, with an indicator on top which is displayed when the magnet descends. As steel loses its magnetic quality at the point of decalescence, which is the proper temperature for plunging, a hot bit held against the indicator will show whether or not it has reached this point.

A debate in the Belgian Chamber of Deputies in Brussels has brought out the fact that the estimated output of the Belgian Congo (Katanga district) for 1923 is 45,000 to 50,000 tons of copper, 250,000 to 300,000 karats of diamonds, and 3,000 kilogrammes of gold.

# 

By John S. Watts \*

Ours being a more or less up-to-date community, we have, along with the other necessities of civilization, our Hebrew Junkman. Although he is now at rest in Abraham's bosom, the naive shrewdness with which he conducted his affairs still affords those who knew him with many a story to pass away an idle moment. Having been born and grown to manhood in Russia, he was not well versed in social etiquette.

In one of his ventures, he enlisted the assistance of one of our business men to help him swing the deal. At a critical moment it became very desirable to close the matter up quickly, and the junkman called on his associate that evening to discuss how this could be accomplished. The Hebrew suggested phoning the sales agent who had the disposal of the goods in question, but his partner objected that the agent would be cross if he was bothered about such a matter at his home in the evening.

"That is all right," said the Hebrew, "I'll phone him and he will only say, 'Oh well, that damned Jew doesn't know any better!'"

The same Israelite, on being quizzed as to his opinion with reference to his people still looking for the coming of The Messiah, replied that when he was in Russia and being driven from pillar to post because of his birth, he prayed daily that The Messiah should come quickly, but that since he came over here where people were good to him, he was in no particular hurry about His coming.

I once sailed as extra engineer on the maiden voyage of a new ship equipped with semi-Diesel engines, and because of unfamiliarity with this type of engine and the engines being new and stiff, was rather nervous about hot bearings during my watch. The crank pits being enclosed made matters worse, as I could not feel the bottom ends nor be sure that they were getting oil. At about six o'clock in the morning, my worst fears were realised by a strong smell of burning oil, and I frantically rushed around trying to locate the hot bearing, but could find no other sign of any, and as the smell soon disappeared I kept the engines going but was greatly relieved when my watch was ended. Everything went along fairly well until the same time next morning when the same smell became evident, accompanied this time by smoke, and by following the smoke I finally discovered the hot bearing to be in fact nothing else but a pan of smoking fat on the galley stove, the galley being ventilated into the engine room under the skylight, so causing the smell to surround the engine.

A butcher shop on Water Street. — A customer looking with disgust at a dirty and discolored side of beef hung there addresses the butcher with "Say, this beef is not fit for human consumption."

Butcher. — "Oh no, that's for ship's stores."

The military occupation of the Ruhr district has reduced the production of coal and coke to such a degree that French metallurgical works are slowly declining in output, coke from other sources being too expensive.

\* Consulting Engineer, New Glasgow, N.S.

# 

The coal production of the world for the last three years is estimated by the United States Geological Survey to be as follows:

| Country                         | 1920.            | 1921.            | 1922.         |
|---------------------------------|------------------|------------------|---------------|
| <b>North America</b>            |                  |                  |               |
| Canada: Coal . . . . .          | 11,812,871       | 10,636,471       | 10,093,055    |

(a) Estimate included in total. (b) Estimated on 11 month's production. (c) Includes the Saar basin. (d) Includes entire output of Upper Silesia from January-May, inc. For months, June-December, only the output of the portion of Upper Silesia awarded to Germany is included. (e) Includes output of the portion of Upper Silesia awarded to Poland for months, June-December, inclusive.

# 

The Geological Survey, Washington, has just issued the statistics of the lead mining industry for 1922. The total production was 532,662 tons, as against 448,589 tons in 1921 and 529,657 tons in 1920. The average selling price per pound was 5.5 cents in 1922, 4.5 cents in 1921 and 8.0 cents in 1920. Over half the lead ore, 202,245 tons, came from Missouri, Idaho producing 91,487 tons, Oklahoma 67,436 tons and Utah 63,130 tons. Canada provided 3,604 tons of ore and 2,900 tons of base bullion in a total foreign supply of 63,914 tons.

Attention has been called recently to a seam of coal of the best steam quality at Silantek, twenty miles from the coast in Sarawak, Borneo, British East Indies. Bunker coal for nearby ports, notably Singapore comes from Japan and Australia at present, and is of inferior quality. The twenty miles of railway required to connect Silantek with the coast have deterred development up to the present.

It is reported in the Soviet press that the production of gold from the Lena district of Siberia has been resumed on a fairly large scale, and that other Russian gold areas are to be worked during the present year.

BY THE JOURNAL'S CORRESPONDENTS

## QUEBEC

**PREVENTIVE MEASURES AGAINST FOREST FIRES IN NORTHWESTERN QUEBEC.**—In view of expected intensive prospecting during the coming summer over promising geological formations in the counties of Temiscamingue and Abitibi in Northwestern Quebec, the Forestry Branch of the Department of Lands and Forests is organizing the district between Lake des Quinze and the Transcontinental Railway to protect against forest fires the valuable standing timber of the region.

The Quebec law for the protection of forests against fire has many provisions. Amongst others it is stated that no one shall set fire to standing trees, to wood-cuttings or slashings between April 1st and November 16th, except for the purpose of heating or cooking. It also provides for spark arresters over the smoke-stacks of all establishments located in the forest.

Anyone wishing to undertake development work on claims recorded in Dasserat, Rouyn, Boischatel and surrounding townships will be well advised to familiarize himself with the regulations enacted for the protection of the forests. Information on this subject will be willingly supplied either by Mr. G. C. Piché, Chief Forestry officer, or by Mr. T. C. Denis, Superintendent of the Bureau of Mines, Quebec.

Preliminary steps in the organization for the protection of the forests against fire have already been taken. Coöperation is assured between the Ottawa River Forest Protective Association, Ltd. and the Forest Fire Prevention Bureaus of the Ontario and Quebec Governments. Look-outs with telephone connections will be constructed at points along the inter-provincial boundary and on elevated points elsewhere in the district.

To enforce the prescriptions of the law, the Forestry Branch is planning to have a full staff of forest rangers to patrol the whole region. These officers will see to it that, besides "bona fide" prospectors only bearers of "travel permits" are allowed to roam in the bush. To keep out all others, a cordon of checking stations will be established. At important geographic points on all travel routes leading to the Rouyn-Boischatel region there will be officers who will make out lists of all persons going in or out. Everyone will have to show his permit and baggage will be searched for firearms. These officers will be special provincial constables and they will also act as game-wardens.

The system of issuing permits to travel in the forest, instituted last summer, is claimed to have been an efficient method of keeping watch on persons entering the forest, and of fixing responsibility in case of bush-fires. This regulation has again been enforced this year by a recent order-in-council. It provides that, between April 1st and November 15th, everyone entering and travelling about in the forest must first obtain a permit. Holders of prospectors' certificates are exempted from this formality, as this certificate is sufficient proof of one's business on lands, the mining rights of which belong to the Crown.

## ONTARIO

**LARDER.**—As a result of some criticism recently directed against the Argonaut Mine, the directors have had the property examined by two independent engineers, and it is stated that their conclusion is favorable to the property. The milling plant is expected to be in operation in May, and will start on a fifty tons a day basis. It is estimated that the reserves above the 500-foot level constitute a two and a half years' supply.

A recent investigation of the Crown Reserve and Associated Gold Fields properties in the Larder Lake district holds out the hope that this district will have at least two gold producers. According to the information available, the Associated has done 800 feet of drifting on the 250-foot level, of which 600 feet is in commercial ore. The shaft is down to a depth of 500 feet, and work on that level has just been started. On both these properties the vein has a width of over 20 feet, and values are reported to run between \$7.00 and \$8.00. Both companies are talking of 500-ton milling plants. The Associated Gold Fields has had a long and unsatisfactory history, and the company has been subjected to a good deal of well deserved criticism. It has an enormous capitalization and while it is very doubtful if the majority of the shareholders will have much chance of realizing on their investment, they will, if the present development continues, at least have a possibility of some return.

The first diamond-drill hole on the Imerson claim in Larder Lake has had to be abandoned, as the drillers found it impossible to reach bed-rock. The casing penetrate 160 feet of sand and gravel before being given up. The property is under option to A. D. Miles, who represents John Taylor & Sons of London, England.

**QUINZE POWER.**—An interesting event will take place in the Parliament Buildings in Quebec on April 25th, when the Quebec Government will lease, by auction, the upper group of rapids on the Quinze River, which is located a short distance from the Dominion Government Quinze Lake reservoir. These rapids have an estimated capacity of 60,000 h.p. The terms under which the power will be disposed of are interesting, and rather unusual. The power will be leased for sixty years for a minimum annual rental of \$8,000, the power going to the one who bids highest above that price. In addition a special tax of 50 cents a h.p. will be collected for all power exported from the Province of Quebec. The successful bidder must deposit \$15,000 before April 21st, as part of a total of \$75,000, which he will be obliged to deposit as a guarantee of certain performances within a specified time. The development of the power must be started within eight months from the date of the signing of the contract, and 20,000 h.p. is to be developed within four years. There has recently been a good deal of speculation with regard to this power, and it is stated that the Hollinger is interested and may be one of the bidders. The last annual report of the mining company showed an item for the cost of surveying this water power. The name

of the Northern Canada Power Company has also been mentioned in connection with it, and it is the general belief that power from there will be supplied to Ontario gold mines.

**PORCUPINE.**—The Porcupine mines have suffered a still further cut in power, and are now getting only about 18 percent of their normal requirements. The situation has never been so serious, but the break-up is liable to occur at almost any time, when there should be a surplus of power.

It is understood that Peninsular Mines has made a contract with the Great Northern Power Company for 700 h.p. from the new plant at Indian Chutes. The clearing for the transmission line has already been commenced.

Thompson-Krist interests are endeavoring to raise enough money in England to finance the paying off of their share of the North Crown expenditures. The company is unable to get its property back until this has been done.

The Goldale will sink the main shaft from 500 feet to 1000 feet. Stations will be cut at intervals, but no exploration will be undertaken until the shaft reaches 1000 feet.

At the Vipond, crosseutting is being done at the 400-foot level to try and cut the veins recently located at 1000 feet. It is understood that the results at the 1000-foot level were encouraging, but did not show any extensive shoots of commercial ore.

The West Dome Lake has recently purchased 20 acres from the Ritchie Veteran Claim, adjoining. They have decided to proceed immediately with the unwatering of the mine, and when this has been done the shaft will be continued to the 1000-foot level.

**COBALT.**—At the recent annual meeting of La Rose, the old board of directors was re-elected, without a dissenting vote. The opposition expected from a Toronto mining brokerage firm did not materialize.

Directors of the Nipissing Mine have declared a quarterly dividend of 3 percent, payable April 20th to shareholders of record March 31st.

**KIRKLAND.**—Directors of the Wright-Hargraves have announced that the company will proceed immediately with the doubling of the capacity of the mill, which will bring it up to between 400 and 500 tons a day. Development work has been exceedingly favorable, and justifies the increase in capacity.

## NOVA SCOTIA

**LABOUR LEGISLATORS ADVOCATE RESTRICTIVE MEASURE.**—Not content with the set-back given the small collieries of Cumberland, the labor party has introduced a bill in the local Parliament which, if passed and enforced, would close every little colliery in Cumberland and hit some of the others in Cape Breton an almost deadly blow. The bill calls for travelling roads 6 feet high and 5 feet wide. On its face it has a semblance of reason but no one knows better than the miner, except it be the coal operator, that the cost of making travelling roads of these dimensions will prohibit the mining of the thin seams. Where the coal seam is 6 feet thick the travelling road must be 6 feet high, and where the seam is 5 feet thick the travelling road can be 5 feet high. Here there is no hardship. But where a seam is say 4 feet six inches thick, there is added cost through the blasting of roof rock. Once broken,

some of this rock falls three or four feet high and sometime higher. Seams thinner than this are at a still greater disadvantage, for besides the cost of blasting there would not be sufficient storage for the rock and it would require to be loaded and sent out of the mine.

**COAL MINING LAWS NEED REVISION.**—That the mining laws of Nova Scotia need to be changed to conform to the new conditions of coal mining is apparent to all who have any knowledge of them or experience in trying to live up to them. Originally they were patterned after the British mining laws, but of late years much has been copied from the mining laws of Pennsylvania. There is no analogy between the conditions of mining in that state and in our Province. The seams of Pennsylvania are nearly all high and lie almost level. Nova Scotia has no level seams, and many that lie at a steep angle. It has a large number of thick seams, but also many thin ones. On the other hand in Britain many thin seams are mined. British miners have had a long experience with such seams at great depths and steep pitches. But while the British mining laws have been models for safety and protection, yet the coal owners have not been hampered in making progress.

A revision of the law must be made before the undersea areas can be properly won. Indeed, present laws governing the undersea districts were all made without experience. Fear of the sea breaking in from some old river bed was the directing motive, and there has been no attempt since then, in spite of all that has been learned, to make these laws practical as well as in the interests of safety.

The laws governing the employment of labor also need revision. Some of them are out of date and others are distinctly anomalous.

## BRITISH COLUMBIA

**ANACONDA HAS OPTION ON MARBLE BAY MINE.**—About a week ago it was reported that the Anaconda Copper Co. was preparing to enter the mining field of British Columbia. This has since been confirmed, reliable reports stating that the Montana company have secured an option on the Marble Bay Mine, Texada Island, and that the intention is to unwater it immediately, preparatory to proceeding with further development. It also is stated authoritatively that the same company is negotiating with a view to obtaining control of the Van Anda Gold Copper Mining Co's, holdings. These are situated adjacent to the Marble Bay Mine and include the Copper Queen, Cornell, Little Billie, and Security.

With the resumption of operations there will be a revival on Texada Island, where industry has been dormant since early in 1921, when work ceased. Up to that time, since 1898, the Marble Bay Mine was a regular producer of copper-gold-silver ore, the copper being chiefly of the bornite variety. Previous to the closing down of the mine a body of ore was discovered by diamond drilling below the 1700-foot level or about 1600 feet vertically below sea level. The management had made arrangements to extend the incline winze already sunk below the 1600-level from near the face of the northwesterly drift on the 1500-level to the new discovery; but the price of copper remained too low to warrant the extension of the workings at that time.

This, it is understood, is what the Anaconda Copper Company proposes doing as soon as the mine and plant have been put in condition. In fact it is given out that the Company is making a close examination of the whole situation with a view, should the possibilities prove sufficiently promising, to establishing the industry to assure the maintenance of output.

**SANDON.**—The American Boy Mine, Sandon, which has been under development for some months, is reported to have 30,000 tons of silver lead-zinc ore of a good grade on the dump, together with some 60,000 tons of first-class milling ore blocked out. The owners have acquired a number of adjoining properties. It is said that in No. 7 tunnel six feet of ore has been uncovered that will average better than 65 percent zinc and 8 ounces silver. At the face of No. 7 tunnel, 800 feet from the portal, it is understood that a blind contact vein, six and one-half feet wide with distinct walls and in a real porphyry formation has been found. Samples have been taken from this running 210 ounces silver and 70 percent lead. This vein has been drifted on for 30 feet. The Company is planning the installation of a tramway and a mill.

**A "POOR MAN'S MINE".**—The Victor, a Slocan property situated near the Wonderful and Monitor Mines, is described as the district's finest example of a "poor man's mine." One car of ore, shipped during the winter, is reported to have given a return of \$5,000. Two men are engaged in stripping and it is estimated that there is \$50,000 worth of ore in sight.

**BRISCO.**—Several cars of ore have shipped to the Trail Smelter from the Steele group, situated on Toby Creek in the Kootenays. This property is being systematically developed by its owners, the Alice Arm Holdings Co., of Vancouver. As a result of recent tunneling and drifting a shoot of "steel" galena, averaging sixty-eight ounces of silver and 82.5 percent lead, has been proved. There also have been uncovered substantial bodies of ore of lower grade. The grade of what has been shipped was from twenty-five to thirty ounces of silver and 35 percent lead. A tramway 1200 feet in length has been installed. Needed improvements have been made to roads and trails with the assistance of the Provincial Government and a bridge has been built across the Columbia River at the town of Brisco, the mine being eighteen miles from this station on the Kootenay Central Ry. New work planned includes the construction of a small mill, while it is proposed that tractors shall be used for hauling ore next winter.

**MORE POWER REQUIRED.**—The West Kootenay Power & Light Co., proposes increasing the capacity of its plant at Bonnington Falls near Nelson from 30,000 to 60,000 h.p. The Company's plant at Grand Forks develops 1500 h.p. One of the principal reasons for this extension is that the Granby Consolidated Mining & Smelting Co. will require additional power for the operation of the plant of the former Canada Copper Corporation which the Company has acquired at Copper Mountain and Allenby the concentrating mill being at the latter point. As the contemplated extension would mean the raising of Kootenay Lake, and probably affect the work now underway of reclaiming the Kootenay Flats, authority is being sought from the Provincial Government and the Company's application is under consideration.

**CANADA COPPER AFFAIRS.**—An order for judgment in

the foreclosure suit of the Equitable Trust Company of New York and the Canada Copper Corporation was allowed recently in the British Columbia Supreme Court, the amount involved being some \$2,800,000. Arrears of interest total about \$300,000. The property will be sold on May 7th, and at this sale it is understood that the Granby Company will be bidders.

P. B. Freeland, resident mining engineer at Grand Forks, a short time ago related the history of Copper Mountain operations and outlined present conditions in the following terms:

"The Canada Copper Corporation, then the B. C. Copper Co., first worked on Copper Mountain in 1905, did some development, and allowed the bond to lapse. In 1911 the same company took options on Voight's claims, adjoining the Copper Mountain group on the north. The Company and Mr. Voight failed to come to an agreement and the options lapsed. Exploratory work on this group uncovered some large copper ore-bodies.

"In 1912 the B. C. Copper Co. again took options on several Copper Mountain claims and did extensive diamond drilling and surface trenching. In the years following, development consisted mainly of tunnelling totaling about 13,000 feet, 6,400 feet of upraises, 936 feet of sinking, 118,000 feet of diamond drilling and 32,000 feet of trenching. The company's holdings on the mountain are 3,192.97 acres.

"The monzonite rocks carry the ore, which consists of chalcopyrite, bornite and pyrite, occupying numerous fractures and also occurring in small grains. The deposition of the ore took place in Jurassic times, and is in part an original constituent of the monzonite rocks and was in part deposited in the fractures by hot solutions or vapors given off by these rocks when they cooled. Within these granular rocks are small masses of highly altered sedimentary rocks (Palaeozoic). These older rocks have been intricately cut by a system of porphyry dikes (granite and quartz porphyry.)

"Chalcopyrite and bornite are the primary copper minerals, associated with hematite, magnetite, and iron pyrites. Some secondary action has taken place in the Helen Gardner claim, distributing chalcocite, native copper, malachite, azurite and cuprite. The main ore-bodies are primary.

"The highly siliceous alumina content is detrimental to direct smelting, and in consequence a 2,000-ton concentration plant has been built at Allenby to treat the ores. A recent review of diamond-drill and development records and an examination of the workings concedes 5,625,980 tons of 1.83 percent copper ore instead of 10,000,000 tons of 1.74 percent copper estimated formerly. The cutting of the estimated ore-reserves from 10,000,000 to 5,635,980 tons is not as serious as it may at first appear. In other words, the probabilities for finding more ore in a deposit of this type are exceedingly good. The property, in spite of all the diamond drilling, has not been as thoroughly prospected as it might have been and when development progresses it is more than likely that additional tonnage will be found and mined.

"The ore-bodies developed lie between an elevation of 3,236 and 4,220 feet, a distance of 984 feet. Some of the drill-holes stopped in ore at the 3,236-foot level. The main haulage level is the 3,170-foot level, or 66 feet below the lowest hole; so the probabilities for

finding more ore at depth appear to be good. The mining of the ore presents some difficulties, inasmuch as the porphyry dikes that traverse the ore zones are generally decomposed and may not stand up under heavy blasting. It is probable that a shell of ore will have to be left on the dikes for protection. The situation is ideal for cheap mining. Ore can be handled by gravity."

**GRANBY INCREASES WAGES.**—An increase of wages at the Anyox Plant of the Granby company took effect on March 16th. Employees whose wages previous to that date were \$4 or over per day received an advance of 50 cents, while those whose wages were under \$4 were allowed an increase of 40 cents. The duration of this new scale will depend on the price of copper.

**TRAIL ORE RECEIPTS.**—Ore receipts at the Trail Smelter for the week from the 15th to the 21st March, totalled 8,603 tons.

The shipments in detail follow:

| Mine                                    | Tons  |
|-----------------------------------------|-------|
| Black Rock, Northport . . . . .         | 165   |
| Company Mines . . . . .                 | 6777  |

|                                         | 8,603 |

### AN OLD-ESTABLISHED FIRM

The story of Holmans, the well-known rock drill makers of Camborne, Cornwall, England, has been told in a number of mining periodicals recently, and a very interesting story it is. The firm originated in 1802, when Nicholas Holman began to make steam boilers for the famous Cornishman, Richard Trevithick, who was one of those who helped usher in the age of steam. These "high pressure boilers" were made to withstand 20 pounds to the square inch, and some of them are still preserved in the South Kensington Museum, London.

The manufacture of rock drills was commenced by the grandsons of Nicholas Holman in 1881, and since that time not only has the modern Holman drill been developed to its present perfection, but the original tiny works have expanded to cover 30 acres of ground, with a normal complement of 1,200 workmen.

Holmans use their machines, as well as building them. For 40 years past the firm have carried out drilling contracts, and there is no doubt that this dual rôle of manufacturer and miner has had much to do with the sound and logical development of their line of machines. They have been used principally in Britain and in South Africa, and also in Canada (where Alfred Herbert Ltd., of Toronto are agents), India, Australia, Spain, and indeed in most countries where modern mining methods are in use.

Research work has always been characteristic of the Holman development, and an extensive research de-

partment serves the works today. During the stress of the war period, this department suffered, but now its activities are being renewed and augmented. Compressors, pumps, drill sharpeners and other mining machinery are also made by the firm. As is usual with British firms, quality is always counted the first consideration.

A number of world's records in rapid mining have been made by aid of Holman drills, particularly on the Rand in South Africa.

### INDUSTRIAL ITEMS

The Northern Explosives, Limited, of Dragon, Que., have opened an office in Montreal, where all their many customers and others interested in high explosive are welcome. The factory at Dragon, on the C. P. R. short line from Montreal to Ottawa, where all kinds of high explosives and other blasting accessories can be supplied, is thoroughly equipped to take care of all mining, contracting and road-building requirements. The address of the new office is 623 Drummond Building, Montreal.

The Kaelin Electric Steam Generator is described in Bulletin No. 101, just issued by the Dominion Engineering Works, Ltd., Montreal, and available on request. The 16 pages of this bulletin illustrate and describe the construction, operation and control of this newly devised mechanism, as well as its field of application. Particularly interesting are the data for comparing the costs of coal and the Kaelin generator for raising steam under various conditions.

The Charter Gas Engine Company of Sterling, Illinois, have purchased the Mietz Oil Engine business, heretofore carried on in New York, and will conduct it henceforth at their plant at Sterling. Until this move is completed the service to the many users of Mietz engines will be conducted from the New York plant.

### PURCHASE OF GOLD ORES

The attention of prospectors and others is drawn to the provision in the Mining Act of Ontario authorizing the Department of Mines to purchase parcels of gold ore taken out by prospectors and others in developing or working mining claims. Arrangements have been made by which such parcels of gold ore, whether large or small, will be accepted by the Temiskaming Testing Laboratories at Cobalt, and paid for according to the schedule provided for the purpose. The Laboratories are operated under the auspices of the Department of Mines.

This offers a first class opportunity for testing the value of ores on a large scale, and also of turning ore of good quality into money for carrying on further development work. By special arrangements, on less than carload lots, freight rates on the T. & N. O. Railway are reduced 50 per cent.

The Laboratories are also equipped for working out the best methods of treatment for gold or silver ores of a refractory or unusual character.

Full information as to treatment charges, schedule of payments, etc., can be obtained from the undersigned, or from A. A. Cole, Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

THOS. W. GIBSON,  
Deputy Minister of Mines.

Toronto, 12th March, 1923

## GREENING'S WIRE CLOTH AND SCREENS

The superiorities that users have come to expect from any article bearing the name Greening results from the highest standards of manufacture plus a long and intimate knowledge of the condition of service under which their products are used.

For more than sixty years the B. Greening Company have kept accurate records of all statistics that effect the wear, service and cost. These statistics are at the disposal of anyone and frequently save purchasers time and money.

THE **B. GREENING WIRE CO., LIMITED**

HAMILTON, ONTARIO  
MONTREAL, QUE. WINNIPEG, MAN.

The contributing factors in making good Wire Rope are:

Men who know how  
The best grade of materials  
The most Modern Machinery

We have all 3 and are producing the goods. Give us a trial.

Our Wire Rope Catalogue is an invaluable reference book and contains many helpful ideas on the care of wire ropes and cables as well as information on the best kind of rope to use on all classes of work. A copy sent upon request.

Our other lines of Manufacture are Wire Cloth for all uses, Perforated Metals, Wire Pulp Mats, Clothes Lockers, Machinery and Window Guards, Pulp Mats, inquiries solicited.

## For Economy Use Hercules Flotation Oil

The proof of the value of a flotation oil lies not in the cost per gallon, but in the amount of concentrate recovered by its use.

Pine Oil is the best frother known, and Hercules Pine Oils have the advantage of complying strictly with specifications and being uniform in every shipment.

We ask you to compare the price and value of Hercules Pine Oil with others on the basis of net cost per ton of ore treated.

We should welcome an opportunity to demonstrate to you the economy which results from the use of Hercules Steam-distilled Pine Oil.

## MINES BRANCH

Department of Colonization, Mines and Fisheries

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, etc.

### MINISTER OF COLONIZATION, MINES AND FISHERIES, QUEBEC

**MINER'S CERTIFICATES.** First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is \$10 and is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

**WORKING CONDITIONS.** During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

**SIX MONTHS AFTER STAKING.** At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

**MINING LICENSE.** The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year, and a fee of \$10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days' labour on each forty acres.

**MINING CONCESSION.** Notwithstanding the above, a mining concession may be acquired at any time at the rate of \$5 an acre for SUPERIOR METALS, and \$3 an acre for INFERIOR MINERALS.

The attention of prospectors is especially called to the territory in the North-Western part of the Province of Quebec north of the height of land, where important mineralized belts are known to exist.

**PROVINCIAL LABORATORY.** Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, Montreal, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

**HONORABLE J. E. PERRAULT,**

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

# BRITISH COLUMBIA

## The Mineral Province of Western Canada

Has produced Minerals valued as follows Placer Gold, \$76,542,203; Lode Gold, \$109,647,661; Silver, \$59,814,266; Lead, \$51,810,891; Copper, \$170,723,242; Zinc, \$24,625,839; Coal and Coke, \$238,289,565; Building Stone, Brick Cement, etc., \$36,605,942; Miscellaneous Minerals, \$1,358,839; Making its mineral production to the end of 1922 show an

### Aggregate Value of \$734,259,619

The substantial progress of the Mining Industry of this Province is strikingly exhibited in the following figures, which show the value of production for successive five-year periods: For all years to 1895, inclusive \$94,547,241; for five years, 1896-1900, \$57,605,967; for five years, 1901-1905, \$96,509,968; for five years, 1906-1910, \$125,534,474; for five years, 1911-1915, \$142,072,603; for 5 years 1915-1920 \$189,922,725; 1921, \$28,066,641; for the year 1922, \$35,158,843.

### Production During last ten years, \$339,280,940

Lode-mining has only been in progress for about twenty-five years, and not 20 per cent. of the Province has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those of any other Province in the Dominion, or any Colony in the British Empire.

Mineral locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with Mining Reports and Maps, may be obtained gratis by addressing.

## Mineral Areas.

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favorable for the occurrence of minerals, 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver mines of Cobalt occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

## Economic Minerals.

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario:—actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluor-spar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, portland cement, brick and tile, meet every demand.

## Mineral Production.

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1921 to be worth \$48,128,387, of which the metallic production was \$27,574,202.

The following figures show the rapid growth of Ontario's mineral industry by five-year periods since 1891:

| Year.         | Value.      | Year.         | Value.       |
|---------------|-------------|---------------|--------------|
| 1891 .. . . . | \$4,705,672 | 1906 .. . . . | \$22,388,383 |
| 1896 .. . . . | 5,235,003   | 1911 .. . . . | 41,976,797   |
| 1901 .. . . . | 11,831,086  | 1916 .. . . . | 65,303,822   |

## Dividends.

Dividends and bonuses paid to the end of 1921 amounted to \$23,140,734 for gold mining companies, and \$84,388,185 for silver mining companies or a total of \$107,528,919.

## Mining Regulations.

A miner's license costs \$5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of \$2.50 or \$3.00 per acre, depending on location in unsurveyed or surveyed territory.

## Assay Office.

The Provincial Assay Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

## Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

## MINING ENGINEERS AND THE PUBLIC

"The bank should reach all the small merchants and the small industries. These small industries constitute the power of the nation and in critical times it is always the small savings which save a people. France has given us an excellent example of this.

"This leads me again to warn the small savers against the underhand dealings of men who go about the country and the city offering to sell securities of all kinds. The money goes and there is no guarantee that it will return.

"The Government has often been taken to task for not controlling the sale of debentures. It would be impossible for the government to do this. We might believe that a security was good and recommend it to the public. Events might show us to have been wrong, then what position would we be in with respect to the public? On the other hand we might doubt the safety of a security and of necessity we would condemn it. We might thus block the establishment of an industry which might perhaps be destined to enlarge our national inheritance.

"The best thing to do under the circumstances is, it seems to me, to establish a campaign of education. The people should be more careful and should accept the advice which men in authority offer to them."

These are the words of Premier Taschereau, speaking in Quebec to an audience of bankers and business men. These brief sentences contain a wealth of suggestion, particularly to those interested in the mining industry.

Last week, in discussing the value of well-directed publicity to the mining industry, we dwelt upon the responsibility of the Department of Mines in Ottawa in this regard. This Department is the central and principal source in Canada of technical information, much of which is at present unused or inadequately used for lack of an officer trained in the art of the publicist. This week we shall discuss briefly the responsibility that rests upon the mining engineer or geologist in private practice, as well as upon these same men as assembled in the Canadian Institute of Mining and Metallurgy.

We engineers pride ourselves upon belonging to a genuine profession, equal in importance, if not in prestige, to any other profession. What is a profession? The Century dictionary defines it as "a vocation in which a professed knowledge of some department of science or learning is used by its practical ap-

plication to the affairs of others, either in advising, guiding or teaching them, or in serving their interests or welfare...The word implies professed attainments in special knowledge, as distinguished from mere skill; a practical dealing with affairs, as distinguished from mere study or investigation; and an application of such knowledge to uses for others as a vocation, as distinguished from its pursuit for one's own purposes."

The application of this definition to the old-established professions, theology, law and medicine, is clear. What does it involve for us of this newest of the professions, engineering? How best can we mining engineers uphold the ideals of our profession and enhance its prestige? To answer these questions would be to write a treatise on the ethics and practice of engineering. We shall call attention here only to one point — a point that is of vital importance, but that has nevertheless escaped the notice of most practising mining engineers.

The definition above implies that mining engineering, if truly a profession, must be "used by its practical application to the affairs of others, either in advising, guiding or teaching them, or in serving their interests or welfare;" and again, that it must be "an application of such [special] knowledge to uses for others as a vocation, as distinguished from its pursuit for one's own purposes." The idea of service to others is predominant in the definition of engineering, as it should be in the practice of engineering.

Present-day Canadian mining engineers are, as a whole, notable for the excellence of their services to their employers. Our mines are now, in general, under competent technical direction — a statement that could not have been made truthfully twenty-five years ago. The general public can rest assured that from now on the mines of our country will remain under the direction of men well qualified to develop them economically and to the utmost limit.

So much for the relation between mining engineers and the mines whose destinies they guide. What about the relation between mining engineers and the public whose interests the mines are meant to serve? Frankly, this relation is so vague and indeterminate that one almost doubts its existence. The public knows little about the miners, and their knowledge of the mines comes mainly through the advertisements of mining stock promoters, the mining stock quotations, and the news paragraphs (mostly inspired) in our daily newspapers. The miners, on the other hand,

are content to scoff at the seriousness and credibility of the public opinion question. They are easily dismissed, and aver that it is no concern of theirs that the word "mining" is understood by the public as synonymous with "gamble" and is intimately connected with the word "crook". By this very attitude the mining engineer demonstrates that he is not seriously a member of a profession; and the prevalence of the idea throughout the body of our mining engineers shows that we have not yet elevated our vocation fully to the dignity of a profession.

If we mining engineers are to take our proper place in the community, we must give more regard to the community itself. We must help circulate the truth about our work, in place of the half-truth or falsehood that now bears the name of "mining" in the public press. We must do our best to exterminate the pestilential breed of "wild-cats" that batten upon the flesh of the mining industry. We must make it plain to the public, as it is to ourselves, that the so-called "mining stock exchanges," as at present constituted, are the merest devices for gambling, and bear little or no relation to the genuine mining industry. We must revise our present dependence upon outsiders for the financial management of our industry, in order to make certain of the exclusion of the charlatans that too often pass current for sound mine promoters; business and financial management should be part of the mining engineer's prerogative and duty.

Premier Taschereau has pointed the way of progress to mining engineers as well as to bankers. We shall do well to consider the public oftener and more seriously, in the interests both of ourselves and of our profession.

### THE PROSPECTOR AND FOREST FIRES

A strong indictment of the prospector's fire-setting propensities is contained in the current issue of the "Canadian Forestry Magazine." Mr. J. R. Booth, of Ottawa, the veteran lumberman and paper manufacturer, now ninety-six years old and still hale and hearty, was interviewed by the editor of the "Canadian Forestry Magazine," and as both are interested in the preservation of our forest resources, the conversation naturally turned to forest fires, which destroy more timber and pulpwood each year than is used in all the mills. Mr. Booth charged the prospector with the main responsibility for this destruction. The prospector and those that follow him do set fires at times, but the responsibility must be shared by many others, and the genuine prospector, in our experience, is seldom directly responsible for a forest fire.

"Take, for example, the Montreal River spruce country, a few years ago absolutely green... Well, it was opened to prospectors... To this day, not a mine or a real prospect has been uncovered on that 1700 miles; but a horde of irresponsible men seeking non-

existent mines have destroyed from one-third to a half of that country. They have ruined as much timber as would have kept the Ottawa mills running for twenty-five years... I know the history of some of our forests for seventy-five years, and I am frank to say that I believe every dollar's worth of mineral taken from forested lands has cost the country a hundred dollars in destroyed timber. Why not make a business-like calculation of the price we pay for letting loose the prospector on the country's fast-depleting stock of timber? The showing would make us rub our eyes."

Thus says Mr. Booth, and in the main says truly. He forgets, however, that already several million dollars in silver has come from Gowganda, in the midst of the Montreal River district, and likewise he has exaggerated the importance of lumbering operations in comparison with mining. He has not recollected that last year the nickel, silver and gold camps of the north alone yielded over forty million dollars in real wealth. The production of ten times this amount of mineral wealth would not, however, excuse the wanton destruction of our forests that is now taking place each year.

Seldom is a forest fire started by a genuine prospector. Following the prospector, however, whenever he makes a strike, there comes a drove of hangers-on, many of them irresponsible and most of them lacking the careful habits of the real woodsman. It is then that most of the damage attributed to prospectors is done. In Northern Ontario, as Mr. Booth notes, the damage has been particularly severe from this cause. However, we hear of the ravages of forest fires in other areas and in other provinces where there are no prospectors, — fires quite as extensive and quite as numerous as in Ontario; so the prospector must be held responsible only along with the camper, the settler, and the lumberman himself. From the prevalence of fires in the lumberman's slash and on the borders of settlement, we would judge that these two are the most prolific sources of forest fires.

Is it inevitable that prospecting should be accompanied by forest fires? Certainly it is not. We hope to see a demonstration of this in the new gold district of northwestern Quebec during the coming summer. In spite of the comparative congestion of men in this area and the presence of hundreds of novices in the woods, it is quite possible that the measures to be taken to prevent fires will be effective. The principal means of preventing fires will be to impress upon each and every person entering the woods the fact of his personal responsibility in the matter, and to ensure that this personal responsibility shall be brought home to him in case a fire is started.

In that part of Ontario described by Mr. Booth, the most elementary precautions against fire were neglected. The area was a forest reserve, which left

the whole responsibility with the provincial government, without the stimulus afforded by private proprietorship. The fire-ranging system was a joke, and no special precautions against fire were taken. It was commonly known, for instance, among the prospectors and others in the area that a burned area would be leased for cutting, by the government, in order to make use of the scorched timber before it rotted. Many fires are laid to this account.

At present there is a rising tide of popular interest in our forests, one of whose principal effects will be, we hope, to stimulate their protection against fire. The precautionary measures thus developed will, we are sure, serve as well to protect the prospector not only from the rare temptation to fire the forest for his own selfish purposes, but from the much commoner dangers attributable to those who follow him along the trails he blazes.

### THE ECONOMIC GEOLOGIST

"Economic geology is the application of geology to economic problems," says Dr. W. H. Emmons in his new text-book. As geology "deals with the materials of which the earth is made, the forces that operate upon them, the structures that result from this operation, the distribution of the rocks forming the earth's crust, and the history of the earth itself and of the plants and animals that have inhabited it during the different ages" (Coleman and Parks), the economic geologist has "some job" on his hands.

More and more, the responsibility for directing the development of the mining industry devolves upon the economic geologist. There are few geologists in this country in these days who are not, in part at least, economic geologists. The science of geology and its practical application are so closely connected that seldom can one study the one without practising the other. Thus it happens that the large majority of our geologists in public employ are working directly for the progress of the mining industry, and that an increasing number of consulting geologists are employed privately to direct the efforts and expenditures of those concerned with mining operations.

Though their duties often overlap, the mining engineer and the economic geologist have separate and distinct fields. It is the engineer's duty to mine and treat the ore from his mine economically and thoroughly, to develop his ore-deposits to their limit and to make the best use of them. He will be called upon to explore for new ore-bodies and to find faulted ones; but his mine is his province.

The economic geologist, on the other hand, is usually called upon to direct primary exploration for mineral deposits, to gauge their prospective value when found, and to direct the development that will prove or disprove their economic worth. His is an unusually delicate task, calling both for sound technique and ex-

perience and for intuitive judgment. He must have in unusual degree the strength of his convictions; a timid man cannot make a good economic geologist. He must have gained a sound knowledge of the principles of business and commerce, lest his conclusions while scientifically sound should be economically infeasible.

The present organization of the Geological Survey in Ottawa takes full cognizance of the duties and prerogatives of its geologists, as well as the direct bearing of their work on the development of the mineral industry. This is indicated clearly by the fact that each of the staff has been assigned a specialty to follow, this specialty usually coinciding with a mineral or group of minerals of economic importance. Of recent years, too, the responsibility that rests upon geologists for leadership in the development of our mineral lands has been met in growing degree by the officers of the Geological Survey. Frank discussion of the geological problems encountered in the proved and prospective mining camps is the order of the day in recent geological reports, and unequivocal conclusions and practical directions to miners or prospectors are included wherever possible.

Dr. H. C. Cooke's article on the new gold area of northwestern Quebec in last week's "Journal" is typical of this development. Dr. Cooke is the Geological Survey's specialist on gold-bearing formations in the pre-Cambrian rocks. In Larder Lake, Matachewan, northern Manitoba, Kirkland, Porcupine, and now in Quebec he has studied the problem of where, how and why the gold occurs. His aim is to convert accurate observations of fact into principles that will guide exploration and aid discovery. In his article he states the facts of this particular case clearly and on them bases conclusions of practical interest to the prospector. These directions for exploration are so clearly and simply stated that they cannot fail to direct the efforts of many of the hundreds of prospectors that will enter the district within the next six weeks.

We are confident that Dr. Cooke's effort on behalf of these toilers in the northern forests will be repaid a thousand-fold. It will serve to crystalize the opinion of other geologists and mining engineers engaged in the field whose experience and outlook have been more restricted than his own. It will direct the bulk of the effort where the chances are best, though it will not prevent a wide-spread search. This will represent a vast saving of time and money that otherwise would be dissipated uselessly.

Just as the well-advertised fact, a year ago, that the Director of the Geological had decided to map carefully this promising gold area in Quebec stimulated a search there by prospectors, so in the present instance will Dr. Cooke's report direct attention where it is best warranted. The geologist once more is proving himself a leader in the development of the mineral industry.

### MINING SOCIETY MEETING

The annual meeting of the Mining Society of Nova Scotia, held this year in Halifax, has been lively and prolific of fruitful technical discussion, as usual. The members of the Society compose a closely-knit fraternity, held together by the bonds of personal acquaintance and friendship as well as by the essential unity of their various occupations in the great coal and steel industries of the province.

There was discussed at some length at one of the sessions the relations between the Canadian Institute of Mining and Metallurgy and the Mining Society. There is no doubt that the present affiliation of these two societies is beneficial, not only to themselves but to the mining industry of Canada as a whole. It is, therefore, very satisfactory to find that a committee representing both organizations has been formed to examine into the various questions of common concern on which there is at present a difference of opinion, and to effect or recommend such adjustments as may be found to be necessary. The aims and objects of the two societies are essentially the same, and no trivial differences must be allowed to come between them.

Mr. George W. MacLeod's description of the Goudreau gold area, which appears in this issue, is an authoritative and unbiassed account of this promising area. Mr. MacLeod has conducted his professional activities as a mining engineer in the area during the past two years, and what he states of the various properties he knows from personal observation.

### LETTERS FROM READERS

#### Golddale Geology

To the Editor.

Canadian Mining Journal,

Sir:

A news item on the Golddale operations at Porcupine, in your issue of April 6th, states that "Geologists seem to be of the opinion that the McIntyre section is covered by a lava cap and that greater depth offers excellent possibilities". When it is considered that these items are widely copied in technical publications, it is unfortunate that a false impression should be given of the structure of the Keewatin area. Recent surveys by Mr. Burrows of the Provincial Survey indicate that the lava flows in this particular section are essentially vertical, having been tilted into that attitude by post-Temiskaming folding. Development in the McIntyre Mine to a depth of 2400 ft. proves this to be the correct assumption.

The Golddale has decided on a program of deep level exploration, it seems to me, on other grounds, connected with the structure of the intrusive porphyry and governed by the generally accepted hypothesis of genetic relationship between the intrusive porphyry and the ore-deposits. The favorable results secured on the 500 ft. level may reasonably be expected to continue to or improve at lower horizons. The 500 ft. level ore-body, however, can be traced on the surface, where economic values are less in evidence. There is no cap-

ping of lava. The Keewatin lavas are older than the period of vein formation. The dips of the lava beds are usually steep but even flat dips would hardly limit the extension of fractures through flows.

Considerable work is in progress on the structure of the Keewatin, both by the Government Survey and mining companies, and a more general dissemination of the results of this work is to be expected in the near future.

Schumacher, Ont.

H.S. Robinson

### THE LATE ALEXANDER DICK.

The mining industry of Canada has lost a faithful servant, the British Empire Steel Corporation a trusted employee, and a large circle of Canadians a friend of sterling qualities and most amiable disposition in the passing of Alexander Dick. Mr. Dick died suddenly, of heart failure, in New York on April 12th while on a business trip there. He has died before time for he was but fifty-nine years old and was in the midst of a useful business career.

Mr. Dick was born in Stellarton, Nova Scotia, in 1864. He was brought up in the coal business, so to speak, and rose from one position to another in the services of this basic industry of his native province until last year he was appointed sales manager for the Dominion Coal Company, and resided in Montreal.

Wherever Mr. Dick went, he made a host of friends. His genial qualities were irresistibly attractive. The funeral service held in Montreal, though ostensibly private was attended by scores of Montreal's prominent business men, anxious to pay their last respects to a man whose personal regard was held high among them. The burial was at Stellarton.

Mr. Dick is survived by his widow and his daughter, to whom the "Canadian Mining Journal" offers its sympathy.

### ANAMORPHOSIS

The clothes he wore were ancient, awful;  
They were more dirty than is lawful.  
His boots, each like a youthful crate,  
Were in a truly wretched state.  
His chin unshaven, hair unshorn,  
Lent him an aspect all forlorn.  
As if to paint the lily, too,  
His jaws were working on a chew.  
I sized him up as merely tramp,  
Whose job it was free meals to vamp.  
My trust in my perception's shaken:  
For I was utterly mistaken.  
A government official, he  
Was also B.A., B.Sc.  
So far was he removed from tramp  
His word was law throughout the camp.  
Respected much and liked he was,  
And this assuredly with cause.  
But my first instinct was to dip  
Into my pocket for a tip!  
I sometimes think there would have been  
A singularly painful scene  
Had I assumed the moral onus  
Of eleemosynary bonus!

J. C. M.

# THE GOUDREAU GOLD AREA

By G. W. MACLEOD\*

## Location

The Goudreau Gold Area is located in the Sault Ste. Marie Mining Division, District of Algoma, Ontario. It lies almost immediately south of the C.P.R. between Missinaibi and Franz. The Algoma Central Railway, running north from Sault Ste. Marie, travels through the center of the field. Roughly the area is twelve miles in width and thirty miles in length. It extends from Dog Lake on the east, in a south-westerly direction to the Magpie River. In width it extends from mileage 170 to mileage 182 on the A.C.R. The limits of the gold-bearing area, however, are by no means established.

In addition to the above railway facilities, all parts of the camp are easily reached by water routes, the entire area being studded with lakes. Last summer the provincial government built an excellent road from the A.C.R. at Goudreau Station to the property of the Goudreau Gold mines, Ltd., a distance of five miles.

A part of this area is owned by the Algoma Central Railway Co. The regulations pertaining to these lands are identical with those of the Ontario Mines Act, except as follows:—

The miner's license costs only \$1.00

Claims, work etc. are recorded at the office of the Railway Company's Land Department.

The following royalty on gold is charged

2% of the value of the output up to \$1,000,000

3% of the value of the output from \$1,000,000 to \$4,000,000

5% of the value of the output over \$4,000,000

## History

Gold was discovered first by W. J. Webb in the spring of 1918, on what is now known as the McCarthy-Webb Property. Mining activities had been carried on for some years previous to this date on the large deposits of pyrites that exist in this section and all prospecting and exploration work done during these years was with the idea of locating either iron ore or pyrites. With the discovery of gold, however, the activities of prospectors were at once directed towards this metal. Staking was largely confined to townships 48 and 49 along the C.P.R. and a number of promising finds were made.

In November, 1920, a discovery was made near the north shore of Godin Lake, in Township 47 and since that date many claims have been staked in this township.

In April, 1921, a spectacular find was made by Thos. Murphy and Jas. Perry in the central part of Township 28, Range XXVI. Following this discovery several hundred claims were staked, covering all this township and parts of the adjoining townships.

As new discoveries were made and the staking around them spread, the various groups of claims became connected and at the present time there is a continuous line of claims, which varies from one to six miles in width and extends over a distance of twenty-five miles.

## Topography

The general topography consists of a series of low parallel ridges with sandy or marshy ground between them. The general strike of these ridges is east and west. A few, however, run north and south. Only one or two of these ridges reach a height of seventy-five feet above the level of the surrounding country. The average elevation of the area above sea level is about 1,200 feet.

The whole country in this vicinity has been burnt over and there is little good timber except in the swamps and along the streams. The northern section is largely sand plain, the growth consisting of young jackpine. With the exception of the ridges and higher ground the rock is covered with sand and gravel. Generally this covering is not deep, but it is responsible for the fact that the discoveries, almost without exception, are confined to the better exposed ground.

## Geology

A large proportion of the rocks in this area are the old Keewatin volcanics. This formation is made up of many successive flows of both the basic and acidic phases of the predominant rock of this period. Between some of these flows there are bands of iron formation, which vary in width from a few inches to many feet. These bands consist chiefly of pyrites, siderite, silica, and iron oxides. They are especially prevalent in the section east of the A.C.R. A common mistake made by those unfamiliar with this formation is to take these various bands, especially the silica, for veins. To one unaccustomed to this or a similar area this mistake is easily made. Many thousands of dollars have already been spent in this district by men who have made this mistake. While it is too broad a statement to say that this formation does not in some instances carry gold values, at the same time experience in this field has shown that it is not productive in any instance known at present of anything approaching commercial gold values. When samples taken from this formation show gold values, close inspection of the places where they were taken shows that small quartz veins of later origin, cutting the iron formation, have been responsible for the gold.

Both the volcanics and iron formation have been tilted to an angle that varies from 20 to 90 degrees. They have been intruded by granite, quartz and quartz-feldspar porphyries, and diabase dykes. The chief gold values have been found in veins or shear zones in the vicinity of either the granite or the porphyries. The diabase dykes are of two varieties, the older, quartz diabase and the younger, olivine diabase. Those of the latter type are the more numerous. Faulting of considerable magnitude sometimes accompanied the intrusion of the older dykes and in one instance a displacement of 3,000 feet was noted by W. H. Collins, of the Geological Survey, Ottawa, who gives an excellent description of these dykes as well as the geology of part of this field in his report of 1918.\*\*

This belt of Keewatin Volcanics is bordered both on

\*\* Geological Survey of Canada Summary Report, 1918, Part F

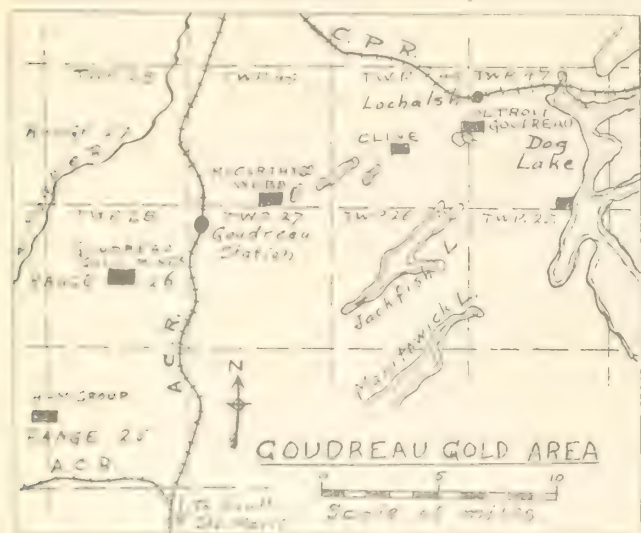

The north and south by large intrusions of granite and acidite masses.

### Description of Properties

#### McCarthy-Webb

This property consists of a group of seven claims located in the south central part of Township 49. It was been examined and reported on by several engineers and a description is included in the geological reports of W. H. Collins,\*\* Ellis Thomson\*\*\* and A. G. Burrows\*\*\*\*.

The gold values are found in quartz veins in shear zones in a wide band of quartz-felspar porphyry. The majority of these veins are narrow and are irregular in extent. There are, however, a large number of them and nearly all carry gold values. There are two sets of veins. The older and most important run with the schisting, i. e. east and west. The other set cut these at right angles. Free gold is visible in many places and good results have been obtained in several places over mining widths. In some instances veins are so close together that they could be mined in one operation. The chief difficulty up to the present is that work on this property has not been concentrated sufficiently to determine the extent of these most important sections.

(Note — Emily Mine is on the shore of Dog Lake)

A large part of the claim is heavily drift-covered and further exploration could be carried on more intelligently by diamond drilling than by further surface work.

The work so far has been confined to the exposed or lightly covered portions, and consists of stripping, trenching and sampling. Tourmaline and pyrite occur in both types of veins.

A good wagon road connects this group with the railway at Goudreau Station. The property is at present under option to a London Mining Syndicate, whose engineers examined it last summer.

#### Michael (Godin Lake) Property

This property (marked Detroit Goudreau on the map) consists of a group of four claims located near the north shore of Godin Lake in Township 47. It is two miles south of the C.P.R. at Lochalsh and is connected to that station by a fairly good road.

The gold values are found in quartz lenses in an ex-

tensive shear zone in a basic volcanic flow. This shear zone is intruded by irregular masses of quartz porphyry and it is in the vicinity of these intrusions that the best values are found.

The shear zone has an average width of 125 feet and has been traced for a distance of 1,000 feet. Gold values are found in practically all parts of this zone and samples taken run from \$0.60 to \$19.00. The higher values are in the quartz lenses and the schist immediately associated with them. The largest of these enriched zones so far uncovered has an average width of seven feet and has been stripped over a length of about 100 feet. The average value here is slightly over \$8.00. The zone has been impregnated with carbonates and the surface shows the characteristic weathering of iron carbonate. In addition to these minerals the schist and quartz contain pyrites, chalcopryite and small amounts of galena. The gold is finely divided and no free gold is visible.

The extent of the mineralization in the known part of the shear zone offers good possibilities for the existence of enrichments of commercial size and value.

The property is under option to the Detroit-Goudreau Gold Development Co. of Windsor. Camps are being erected and diamond drilling will be commenced this month.

#### Goudreau Gold Mines, Ltd.

This company was organized to take over a group of twelve claims located in the central part of Township 28 Range XXVI. The company is capitalized at \$2,500,000, shares being of \$1.00 par value. The owners of these claims received as a purchase price, 1,500,000 shares, which were issued to them as fully paid.

The geology and description of this property is included in the reports of A. G. Burrows 1921, and Ellis Thomson, 1921.

The vein on the surface varies in width from one to ten feet and free gold is visible in many places. An up-to-date mining plant has been installed, including a compressor, two hoists, blacksmith shop equipped with a sharpener, assay office, camps, office, etc. Electric power is obtained from the hydro-electric plant at Steep Hill Falls on the Magpie River.

Two shafts, five hundred feet apart, have been sunk on this vein and these shafts have been connected by a drift on the two-hundred-foot level. This drift has been extended in both directions so that its total length on this level is about 1,000 feet. Free gold was encountered in many places during the sinking of the shafts. At present one of these shafts is being sunk to the four-hundred-foot level and when this is completed the company intend to carry on the same exploration work as was done on the two-hundred-foot level. It is not expected that plans for a mill will be considered until conditions on the 400-foot level are known.

During last summer the provincial government built an excellent road connecting this mine with Goudreau Station, a distance of five miles.

#### Emily Mine

This property, located in the southern part of Township 47, was at first not considered to be in what was strictly the Goudreau Area. It lies about fifteen miles east of Goudreau Station and a considerable distance separated it from the Goudreau claims. In the past few years, however, discoveries have been made and claims staked in this direction so that almost a continuous line of claims now connects it with Goudreau.

\*\* Geological Survey of Canada, Summary Report, 1921, Part D.

\*\*\* Canadian Mining Journal August 5th, 1921, p. 621.

It was discovered in 1901 and during the years 1901 and 1902 the owners (now the Algoma Steel Corporation) sank a shaft to a depth of 56 feet and put down three diamond drill holes. Owing to financial conditions, all operations were suspended in 1903 and have not been resumed.

Definite information as to the value of this property is lacking, but from a milling test of four and one quarter tons of ore, a recovery of \$30.16 per ton was made and \$18.00 per ton remained in the concentrate and tailing. About \$18,000 was spent in the development work. A sample taken by the writer in 1918 from the vein across three feet gave \$44.00 in gold. Most of the surface trenches and pits are filled in, but it would appear that the vein, of rusty quartz, is at least four feet wide and extends for several hundred feet.

Several attempts have been made to option this property from the present owners, but without success.

### Cline Group

This group is located in the central part of Township 48, and is among the early discoveries in the camp. There are several quartz veins, some of which contain visible gold. On one of these veins a pit has been sunk to a depth of 25 feet.

Most of the veins are narrow but one or two are several feet in width. A large part of these claims is heavily drift-covered and it is difficult to trace the veins any distance. Sufficient work has not been done as yet to determine the value of any of the present discoveries.

### Morrison (Cabin Claim)

This claim is owned by the Algoma Exploration and Development Company of Sault Ste. Marie. It is located on the north shore of Goudreau Lake in the south west corner of Township 49.

Free gold is visible in narrow quartz veins in a rusty shear zone. As with the Cline property, this claim is drift-covered and work is carried on only with difficulty. This discovery, while it has promise, has not been traced far enough to enable a statement to be made as to its value.

In addition to the properties mentioned above, there are many claims on which promising discoveries have been made but on which not enough work has been done to prove their value.

Among these are McCormick, Fuller-Black and McCaul in Township 48, Banville, Page and Gutscher groups in township 28 Range XXVI, and the Myhill-Hasselbring claims in Townships 28 and 29, Range XXV.

Several syndicates have been formed to exploit some of these discoveries and considerable activity is anticipated in this camp during the coming season.

Aside from the favorable geological conditions that exist in this area, the camp has many things in its favor that are seldom found in new camps. It is made easily accessible by two railroads, one of which, the A.C.R., runs through the heart of this field, no part of the area being more than seven miles from either one or other of the railways. Cheap electric power is already available to many parts of the camp and could be easily extended to any required point in a short time. There are two hydro-electric powers already developed, which can furnish 2,500 horse-power. One of these plants has sufficient reserve to allow for the development of 30,000 additional horse-power.

Roads are already constructed through part of the camp.

Accurate geological information is available from reports by competent government geologists, a geological map of the district is being made at the present time and should be available shortly.

Exploration work carried on in this field under competent supervision and planned on a sound basis is a legitimate undertaking and is well warranted. The present discoveries indicate the probability of another camp being added to the list of Northern Ontario's gold producers.

### COMPARISON OF FATALITY RATES FOR PITCHING COAL SEAMS AND LEVEL SEAMS.

That the hazards of coal mining are greater in pitching seams than in level workings is indicated by a comparison of the accident experience of the anthracite mines in Pennsylvania with that of the bituminous mines in the same State, made for the United States Coal Commission by W. W. Adams, statistician, Bureau of Mines. Moreover, the difficulties attending mining in the anthracite field, where most of the beds incline considerably from the horizontal, result in a smaller production of coal per employee underground than in the bituminous region where nearly all of the mines are level or of a gentle dip.

During the 11-year period, 1911-1921, the number of fatal accidents in properties to the number of men employed underground was 40 per cent greater in anthracite mines than in bituminous mines. During the same period the anthracite employee averaged only two-thirds as much coal per day as the bituminous worker. It should be stated, however, that since May 1916, the 8-hour day has prevailed in the anthracite field, while prior thereto the 9-hour day was the standard; in the bituminous field most of the men have been employed on the basis of eight hours per day since 1917, but before that year many of them had been employed on the basis of nine and ten hours per day.

The accident experience of the anthracite and bituminous fields of Pennsylvania may be compared with peculiar propriety because the laws relating to the classes of mines, although necessarily differing in some respects, have been uniformly interpreted and enforced by a single department of the State government. In other words, differences in State policy or in law enforcement, which may sometimes constitute an intruding factor in comparisons between mines located in different States, do not enter into a comparison between the anthracite and bituminous mines of Pennsylvania.

During the eleven years 1911-1921, the accident rate at anthracite mines in Pennsylvania was 5.056 per thousand men employed underground as compared with 3.588 at bituminous mines in that State. The actual number of fatalities underground and in shafts was 5,635 at anthracite mines and 4,588 at bituminous mines.

The 1923 prices for the Lake Superior iron ores are 50 cents a ton in advance of those of last year. This may have a beneficial effect in helping to stimulate the production of iron ore in Ontario, where the only serious obstacle to the mining and beneficiation of native ores is the enhanced cost of the product.

# The Matachewan Series and its Pre-Cambrian Relations

In northeastern Ontario, as is well known, the pre-Cambrian consists of a great variety of both igneous and sedimentary rocks that represent a vast period of time. In this region are also to be found some of the world's greatest gold, silver and nickel deposits. The age and structural relations of the rocks have been closely studied during recent years chiefly owing to their bearing on economic problems, and it has been found that owing to the variety of ore occurrences it is necessary to have a more detailed knowledge of the rocks than is necessary in most regions if prospecting and mining problems are to be satisfactorily solved. There is need of a knowledge of what rocks are genetically or structurally connected with certain ores and those that are not. For example, an older series of sediments, the Timiskaming, is found to be structurally related, at least, with the occurrence of gold deposits that are now productive, and certain acid rocks are genetically related to the same deposits. On the other hand, a newer series of sediments, the Cobalt series, is younger than the gold deposits, but in it has been found a high percentage of silver ores. The silver deposits are genetically connected with certain diabases, the Nipissing series, that occupies large areas in the region.

It is difficult to distinguish certain igneous rocks from others that may be either younger or older, unless they are found in contact with rocks whose ages are known. The same may be said of certain sedimentary rocks of the region. But for economic reasons it is necessary to determine if possible the age relations. Prospectors, for instance, have spent time in searching for silver deposits in diabases that they mistook for the Nipissing diabase but which were really of much greater age. Similarly, older porphyries have been mistaken for the newer, that are associated with gold deposits.

A good example of a series of older diabases that have in one or two areas, at least, been mistaken for the newer Nipissing diabase is recorded by Mr. A. G. Burrows in his reports on the Matachewan and Gowganda areas. Speaking of certain diabase in the latter area, this author says:

## Post-Algonian and pre-Cobalt Series

"Diabase occurs abundantly in parts of the area. The Keewatin and the intrusives (granites, syenite and porphyry) are cut by numerous dikes of diabase; whereas in the rocks of the Cobalt series these dikes are quite rare. In the vicinity of the Davidson claims there are several dikes of diabase that lie unconformably below the basal conglomerate of the Cobalt series. These dikes intrude the orthoclase porphyry that has been classed with the Algonian intrusives. It is probable that most of the dikes are post-Algonian and pre-Cobalt series in age.

"The dikes ordinarily are of normal type, medium-grained, showing chiefly plagioclase feldspar and augite with some interstitial quartz.

"Occasionally porphyritic varieties that contain

large phenocrysts of greenish feldspar up to two and three inches in diameter are observed. One of these occurs on the north line of Alma, 20 chains west of the second mile post. It contains greenish porphyritic feldspar in a coarse matrix of labradorite and augite with magnetite.

"There are several dikes of porphyritic diabases intruding Keewatin rocks along the trail north of Davidson creek.

"On the east shore of the southwest bay of Squaw lake in the Indian reserve there is a hornblende diabase. Small rods of plagioclase are set in crystals of hornblende and hypersthene. Interstitial quartz is abundant, and magnetite occurs in small grains." \*

Similar observations have been made by Dr. H. C. Cooke on the occurrence of diabase dikes in the Matachewan Area. \*\*

Of the same series of rocks in the Gowganda area Mr. Burrows says:

## "Pre-Cobalt Series Dikes"

"There are numerous dikes of diabase that are at least older than the Cobalt series. They occur in profusion throughout the Keewatin area northeast of Gowganda townsite, east of Millar lake and elsewhere. These dikes have an approximate north and south strike. They are fresh-looking rocks, and except by their association are difficult to distinguish from similar-appearing dikes that occur in the Cobalt series and that occasionally intrude the Nipissing diabase. They generally contain some quartz grains, but on the whole are darker-looking than the quartz diabase of the sill. They show a somewhat rusty surface, whereas the sill diabase usually has a lighter-coloured oxidized appearance. Porphyritic texture is not uncommon in the dikes, with phenocrysts of feldspar varying from an inch to three inches in length. Such porphyritic texture is not recognized in the diabase sill, and this criterion will serve to distinguish the dikes from the sill where only scattered exposures occur through the drift and relationships cannot be seen. The dikes occurring rarely in the Cobalt series and those that cut the diabase sill strike more nearly east and west than north and south. A number of north and south dikes intruding the syenite-porphyry, which is considered of Algonian age, were observed in the Matachewan area. No acid intrusive rocks that seem to be of Algonian age occur with similar dikes at Gowganda, but the north and south trend and nearness of localities together with the similarity of appearance suggest that the Gowganda dikes are probably also of post-Algonian age. This would place these dikes between the Algonian and Cobalt series in age, and younger than the basic intrusives called Haileyburian in the vicinity of Cobalt.

\*The Matachewan Gold Area, Ont. Dept. of Mines, Vol. XXVII, Part I, pp. 229-30, 1918.

\*\*Geology of Matachewan District, Geol. Surv. Can., Memoir 115, p. 33, 1919.

"The dikes have no special characteristics, being of ordinary diabase consisting essentially of plagioclase and pyroxene, with or without interstitial quartz. No olivine was observed in sections examined. Two porphyritic dikes are very striking in appearance, one on the transmission line, claim H. F. 209, and the other crossing the main road, on claim T. C. 458, west of Leroy lake. The former of these is older than an adjacent diabase dike with similar north-south strike.

"The dikes are not of economic importance as a source of silver since they are much older than the diabase sill. Considerable prospecting was done on them before their age relations were known. Unless in proximity to the sill the possibility of silver-bearing veins being found in them is remote. One of the most interesting localities where the dikes occur is on claims W. D. 961 and W. D. 964. Here they intrude a quartz-porphry, or felsite, and iron formation, but are overlain unconformably by conglomerate of the Cobalt series. All these formations are intruded by a younger quartz-diabase dike that strikes a few degrees north of east". \*\*\*

#### More Northern Occurrences

Within the last two or three years Mr. D. G. H. Wright has mapped, geologically, an area that lies over forty miles northward of Gowganda and has found there the same series of dikes described by Mr. Burrows in the Matachewan and Gowganda areas. Mr. Wright's report is now in the press. It is entitled "Geology of the Watabeag Area" and will form part VII of Vol. XXXI of the Ontario Department of Mines' publications. Of the dikes Mr. Wright says, in the marginal notes on his map:

#### "Post-Algoman and Pre-Cobalt Series"

"Dikes and sills of diabase belonging to this age are to be found with a widespread distribution throughout northeastern Ontario. The dikes definitely of pre-Cobalt series age are frequently characterized by phenocrysts of labradorite feldspar sometimes one or two inches in diameter. The phenocrysts have a greenish-yellow waxy appearance, due principally to sericitization and kaolinization. Other diabases which petrographically are practically identical with the Nipissing diabase are also found. The dikes usually strike in a northerly direction."

Owing to the wide distribution of this igneous series and the importance of distinguishing it from the Nipissing and other diabases, etc., it would appear advisable to give it a distinctive name so as to avoid using the phrase "pre-Cobalt and post-Algoman" when referring to it. Mr. Burrows proposes to call this group of rocks the Matachewan series.

The Eozoic or pre-Cambrian rocks in northeastern Ontario, as regards age relations, may be classified as shown in the following table, the names of the igneous groups being placed in parentheses.

#### EOZOIC OR PRE-CAMBRIAN

|       |   |                                            |
|-------|---|--------------------------------------------|
| Upper | { | Keweenawan — Nipissing diabase,            |
|       |   | etc., of N.E. Ontario                      |
|       |   | Animikean—sediments of Cobalt series, etc. |

|        |   |                                            |
|--------|---|--------------------------------------------|
| Middle | { | Great Unconformity                         |
|        |   | (Matachewan)—diabase dikes etc.            |
|        |   | (Algoman)—granite, porphyry, etc.          |
| Lower  | { | (Haileyburian) — lamprophyre, diabase etc. |
|        |   | Timiskamian - sediments                    |
|        |   | Great Unconformity                         |
|        | { | (Laurentian)—granite, etc.                 |
|        |   | Grenville—limestones, etc.                 |
|        |   | (Keewatin)—basic lavas, etc.               |

It will be noted that the three subdivisions, Lower, Middle and Upper, are based on two great periods of erosion, viz., those in which the Timiskaming and Animikie sediments, respectively, were deposited. The sediments of Grenville age, consisting of greywacké, quartzite, iron-formation, limestone and other fine-grained materials, are believed to be in part, at least, contemporaneous with the submarine lava flows that represent the Keewatin. No undoubted evidence of land or surface erosion has been detected, the sediments representing chemical deposits and fragmental material that may have been produced during the eruption of the lavas, certain fine-grained fragments being changed to clay, etc., through decomposition in the sea water. One of the chief characteristics of the Grenville sediments is their fineness in grain.

There is an unconformity between the Animikean and Keweenawan sediments in the Lake Superior country, but it is of minor importance compared with that at the base of the Animikean or the Timiskamian. There are minor unconformities within the Animikean. In northeastern Ontario Keweenawan sediments have not been recognized. The Nipissing diabase is considered to represent the Keweenawan lavas. The age of the olivine diabase and other dikes younger than the Nipissing cannot be definitely determined in the northeastern region.

Toronto, March, 1923

W. G. M.

#### NEW SAFETY REPORT

Safe Practices Pamphlet No. 54 entitled "Handling Material" has just been published by the National Safety Council, 168 North Michigan Ave. Chicago. Handling material is generally recognized as one of the greatest safety problems in industry and according to state reports handling material by hand causes more accidents than all machinery. The pamphlet is divided into the following main divisions: Power Trucks, Hand Trucks, Piling Material, Handling by Hand and Safe Habits of Work, each of which is again subdivided into paragraphs dealing with the different types of equipment used and the different methods employed in handling various types of material. The pamphlet is freely illustrated with photographs and diagrams. A large number of industries are covered and owing to the fact that handling material is common to every industry, the pamphlet has an unusually wide range of usefulness. The experience of many members of the National Safety Council was contributed in the preparation of the pamphlet and the assistance of a committee of seventy-five Safety Engineers was employed in editing and revising the material.

The Canadian Pacific Railway is watching closely the development of the new gold area of northwestern Quebec, in case the extension northward of its Temiskaming branch should be warranted.

# THE MINING SOCIETY OF NOVA SCOTIA

ANNUAL MEETING IN HALIFAX,  
APRIL 9th TO 12th

The 31st Annual Meeting of the Mining Society of Nova Scotia was held in the Board of Trade Rooms, Halifax, from the 9th to the 12th of April, inclusive. About fifty members were in attendance, most of them from the mining districts of the Province. Visiting members from other parts of Canada were, Dr. W. H. Collins, Director of the Geological Survey and Mr. J. A. Dresser, Montreal, President of the Canadian Institute of Mining and Metallurgy.

The following officers were elected for the coming year—

President, C. M. O'Dell, Sydney, Chief Resident Engineer of the British Empire Steel Corporation.

1st Vice-President, Alex. S. MacNeil, Glace Bay, Superintendent Dominion Coal Company.

2nd Vice-President, F. W. Gray, Sydney, Asst. to Vice-President of the British Empire Steel Corporation.

Secretary-Treasurer, E. C. Hanrahan.

Councillors: T. J. Brown, Deputy Minister of Mines, Halifax; R. E. Chambers, New Glasgow; W. H. Graham, Sydney; Walter Herd, Sydney; D. H. MacDougall, Sydney; Col. Thos. Cantley, New Glasgow; K. H. Marsh, Sydney; H. J. MacCann, Sydney; Hon. Robt. Drummond, Stellarton; Malcolm Blue, Stellarton; Alex. MacEachran, Glace Bay; D. H. McLean, Glace Bay; D. J. MacDougall, Stellarton; H. B. Gillis, Sydney; Wm. Bischoff, Sydney; J. C. Nicholson, Springhill; Geo. D. MacDougall, (ex officio, as Past President.)

Following is the address of Mr. Geo. D. MacDougall, President. With a faculty of terse and concise expression, and the knowledge that enables him to make sound, practical comment on every subject discussed, and withal a big heart overflowing with desire to help all men showing any inclination to help themselves. Mr. MacDougall was, and is, a great inspiration to the Society whose work he has guided with skilful hand.

## Presidential Address

"Gentlemen of the Mining Society of Nova Scotia:—  
"I appreciate very much the privilege (which is, I think, unique in the history of our Society) of preparing three annual addresses, this being the third.

Last year in my address I opened up the question of lack of attention given to Nova Scotia by the Geological Survey of Canada, and I was authorized by the Annual Meeting to take such steps as might seem necessary to the end that this situation might be corrected. Dr. Collins, Director of the Geological Survey, was good enough to come to Sydney to discuss the question involved, with me and with other members of the Society. A competent committee was appointed and this committee will report at this meeting and I am sure you will be satisfied with the undertakings of the "Survey" and will approve the comprehensive suggestions made for future activities.

"Perhaps no question, not even excepting the railway question, is of greater importance to the people of

Canada today than the fuel question. I might more properly say the coal question, for after all coal is our only important fuel. We, of course, recognize the tremendous importance of our water powers as a source of energy, but as a source of heat for commercial purposes they do not affect the main question. The annual meeting of the Canadian Institute of Mining and Metallurgy devoted a whole day of their recent annual meeting to this question. The Parliament of Canada is investigating it through a special committee of the Senate. The press of the whole country has been filled with articles relating to this same subject. These facts I mention only to indicate the importance that has been and should be attached to this problem. One might say well: 'Nova Scotia is all right; let the rest of Canada look out for itself, as best it may. What do we care?' That is not a correct attitude. We care very much and for more than one reason.

(a) We are interested because we are an integral part of the Dominion and Canada's problems are our problems.

(b) We are interested because there is a very considerable inter-relation between our railway problem and our coal problem.

(c) We are interested because the success of Nova Scotia depends in a very considerable measure on the mining of coal and that part of Canada contiguous to the St. Lawrence River is our principal and natural, as well as our present market. There may be other good reasons, but this last is the one most interesting to us at this time.

## The Fuel Problem

"What is Canada's Fuel Problem? Briefly stated it is this. From the Pacific Coast to slightly east of Winnipeg, coal can be procured from British Columbia and Alberta. From Montreal, or slightly west, to the Atlantic Ocean coal can be procured from Nova Scotia. This leaves a gap representing approximately the Province of Ontario, or at least that portion comprised between the eastern and western extremities of the Great Lakes, which has no coal fields and has been heretofore supplied with coal from the United States. The total coal requirement of this district is roughly 10 to 12 million tons a year, of which about 25 per cent is anthracite; the amounts for the Province of Quebec will be about half these. Inasmuch as the total output of all Canadian collieries, as shown by the Dominion Bureau of Statistics for 1922, was slightly over 15,000,000 tons with imports above exports of 16,000,000 tons, there can be no talk of relief from within, on our present basis of consumption, production and methods of use.

"Inasmuch as the United States' future supply of bituminous coal for export is better assured than their supply of anthracite coal for export, we should most properly consider the replacement of the anthracite requirements.

## Coke in Montreal

"It is well established that coke made in the modern by-product oven is an equivalent of anthracite coal. The particularly good feature of the manufacture of coke is not only its use of the slack, which is high in friable coals, but the recovery of the by-products such as gas, tar, sulphate of ammonia, benzol and such further derivatives as exigencies of business may justify.

"We are glad to note that following a recent meeting of shareholders of the British Empire Steel Corporation an announcement was made to the effect that the matter of establishing a coking plant at Montreal was being investigated.

"It is not my intent, nor do I believe our Society at the moment wishes, to suggest a solution of this question, but we are quite willing to assist all legitimate efforts to discover the solution. We are glad to note the efforts of the Government of Canada and of Parliament.

“Much has been written for our scientific societies setting forth Canada’s position in regard to our coal reserves and output, and Mr. F. W. Gray in a clear-cut article points out that 10,000,000 tons per annum should be considered a maximum Nova Scotia output. Our present yearly outputs are under 6,000,000 tons.

"Speaking broadly, if Canada is to be independent in the matter of coal supply, her production must be more than doubled. This is a serious problem, involving the unfortunate 'freight rate' question, and must be well considered before being advanced with any degree of seriousness. It would seem as if Canada must be dependent for some considerable time at any rate upon imports of fuel for the comfort and prosperity of its citizens.

## Gold

"We are glad to note by the Mines report for last year some small, but nevertheless hopeful, signs of activity in our gold fields. A report by Mr. Beveridge suggests that 'gold bearing leads' are not of a shallow nature as was indicated by Mr. Rickard some years ago. It is to be hoped that close study of these fields by competent men will bring this industry back to its position of the year 1900.

"It might perhaps not be too much to suggest that the establishment of an assay office, possibly in connection with the Nova Scotia Technical College, where prospectors could, free of charge to them, have samples assayed, would be a considerable stimulus.

"It was a matter of great satisfaction to the members of this Society when the then Government of Nova Scotia selected Mr. T. J. Brown, one of our Past Presidents and most active members, as Deputy Commissioner of Mines. This satisfaction was increased when Hon. E. H. Armstrong, who for years held the important portfolio of Minister of Mines, succeeded to the Premiership. As your President I was pleased to extend my felicitations and assure both gentlemen of the active support of the Mining Society.

"I desire to tender my thanks to the whole membership not only for the confidence expressed in electing me President of your Society, but for the generous assistance rendered me at all times in directing your business. I believe the mining industry in Nova Scotia is on the eve of better days and it now remains for us to exert our best efforts of skill and education to the end that the prosperity our Province deserves may

become (insofar as we can make it possible) an actuality."

Mr. Mayall is sure of one thing, and that is that successful flushing can be done, provided the necessary materials can be obtained cheaply and in sufficient quantity to fill up the sections from which coal has been extracted, and sufficient additional quantity of coal won from these sections to cover the extra cost of operations. Professor Sexton pointed to the possibilities of compressed air instead of water as a vehicle, which when liberated could be used for ventilation and save the cost of having to pump the water back out of the mine.

### "The Evolution of the Wash House"

This paper by W. H. Graham, Superintendent of construction, was interesting from the fact that the finest wash houses, perhaps, at any Canadian collieries are to be found in the Glace Bay District, built by Mr. Graham. As with many another expert, the latest building, which is by far the best, shut out Mr. Graham's view in retrospect, and he failed to look back to the beginnings. A better builder than he is a painter, his picture did not fully describe what he had really accomplished. There was no comparison with the wash houses of early days, many of which he either modernized or pulled down. He did, however, emphasize the advantage of the hollow wall in the construction of large buildings. He pointed out its durability, its cheapness and its comforts, and possibly, after all, these more than any other features, interest the average operator of large concerns. But when to the returned soldier, who, under military orders had acquired the habit of bathing, he gave the credit of bringing the use of the wash houses up to 100 per cent, he forgot his own labors in making the building so attractive, so clean and comfortable, so well ventilated and heated, and so well fitted up with cold and hot shower baths, that workmen could not refrain from their use, even if they would. The miners of these collieries, with their modern bath houses, have come to look upon them as part of their daily life, and could not now go on without them.

### Discussion of Mr. Gray's Notable Paper

That part of Mr. F. W. Gray's paper of last November relating to Nova Scotia was read and discussed. Most favorable comment was made on its scope and nature, and all present felt that Mr. Gray pointed the way out of one phase of the difficulty surrounding Canada's fuel problem. Some believe that through the by-product process an equivalent to anthracite has been found. Good coke, it was stated, is better than anthracite; eight tons of it giving as much heat or power as ten tons of hard coal. There is little residue left in the way of ash. The other features, such as the converting of coal into gas, or extracting all its volatile constituents in the way of oils, etc., were commented on. Mr. MacEachran, Chief Inspector of the Dominion collieries, touched on the increased power developed when coal is converted into gas, and used direct as a motive power. He also referred to the surprising results from the use of lignite thus treated.

### "Rescue Breathing Apparatus"

This most interesting paper, from Mr. J. C. Mackie, chemist for the British Empire Steel Corporation, stressed the necessity of having the lungs of the operator of any type of self-contained breathing apparatus thoroughly washed out by the use of pure oxygen before beginning to put it on. If this were not done, serious results might follow, especially if the oxygen

supply failed. It was pointed out that many cases of carbon dioxide poisoning were actually due to some other cause, and now generally believed to be a mixture of oxygen with nitrogen and other gases. The discussion on this paper brought out some valuable information on the successful treatment of men overcome by gas in a coal mine or any similar place, when carbon dioxide mixed with oxygen is used for resuscitating, rather than pure oxygen. One member stated that many cases of gas poisoning when treated with oxygen die from pneumonia a short time afterwards. The principle of washing out the lungs with pure oxygen is one followed out at all well equipped rescue stations.

### Dr. Collins' Address

The Committee on Geological Survey at the first session asked to have their report lie over until Dr. W. H. Collins arrived in the city. This was agreed to, and Mr. F. W. Gray submitted the report the following morning. After it was read, Dr. Collins, in his own quiet, undemonstrative manner, addressed the members. Even though competing against the noise of many of the vehicles of Halifax rushing and rumbling over a granite block pavement, Dr. Collins succeeded in carrying his hearers with him into the wilds, where pioneer work was being done, so that the prospector, and after him the operator, might with some degree of certainty follow and dig the stored-up treasures of ages. He reviewed the work that had been done in the way of survey and map making; he told of the difficulty encountered, of the progress made and of the present intentions of the Geological Survey. It was fully recognized that in the light of the research work done in Nova Scotia during the past year, the Geological maps required to be brought up to date. This matter was now being attended to; but to be permanently completed, some further work was necessary. He further dealt with the wisdom of concentrating on certain sections of the province, such as those known to contain oil shales, gypsum and other such minerals. The saline areas, with their old sea deposits would receive early attention, and the gold areas would come in for further investigation. Dr. Collins had to answer many questions, and he succeeded fairly well in satisfying the members of the Society. A committee was appointed to meet with Dr. Collins, who stated he had the duty of looking after the Geological Survey work of Nova Scotia, and would be pleased to have the advice of all who could help him. Dr. Pierce followed and in a vivid and forceful speech pointed to the necessity of free circulation and quick issue of the geological maps of Nova Scotia.

### Mr. Dresser's Address

Mr. John E. Dresser of Montreal, President of the Canadian Institute of Mining and Metallurgy, addressed the members on the advantages of belonging to an organized body, such as they were. The need of unity from east to west of Canada and the necessity for team work and concentrated action at critical moments in the life of the industries represented, was strongly emphasized by this stalwart, rugged-looking Canadian. His appeal was to the best and highest in the men he addressed.

If the writer is not mistaken Mr. Dresser is a big man in every way. He was ably backed by Professor Sexton of the Technical College, Halifax. What Nova Scotia workmen owe to this fresh-faced, cheery, hard-

working educationist, we will not here try to say, but the debt is great, and the fact that the professor was an active member, taking part in the discussions on the several papers, added much to the instruction and information of the members.

Hon. Robert Drummond with his eighty-three years, vigorous in mind, keen in debate, progressive and optimistic as the youngest member present, was heard with pleasure and delight, and when it came to a battle of wit or wisdom, he easily held first place.

Mr. V. A. Paton, Chairman of the Compensation Board, was present, and addressed the meeting. A man of ability, he has convictions, with the courage necessary to put them into execution. He is in the right place, and with his large experience, is in a position to help apply a remedy to the evils creeping into the Compensation Department at the places where accidents occur. I would not venture to say there are any of these evils in his office at Halifax.

#### Accident Prevention in Coal Mines

This was a well-written, scholarly and practical paper, by J. R. Dinn. Mr. Dinn is manager of No. 4 Colliery, Dominion Coal Company, and holds the record for low accident rate. During one whole year there was not one fatality in his mine, which is a very large one. He emphasized the necessity of co-operation between the mine officials and the mine workers. Close personal contact, educational propaganda, thorough training and instruction were all necessary. The higher percentage of accidents occurring on the haulage ways, and those caused by falls of roof rock and stone, were pointed out. Many other suggestions were offered. The fact that there was very keen discussion on this paper, a large number of the members taking part, showed the interest it aroused. Mr. Dinn was thanked for his able and very practical presentation of a very difficult problem.

#### The Mining Society and the Institute

A discussion arose over the relationship between the Mining Society of Nova Scotia and the Canadian Institute of Mining and Metallurgy. It was pointed out that the financial arrangement between these bodies was not in the interest of the Nova Scotia society, and tended towards a small membership. There was no incentive to increase the number of members, seeing that all additional monies coming from those who joined, after the hundred mark had been reached, went to the Institute. Mr. Dresser and Dr. Collins both assured the members of the Society that there was no intention on the part of the Institute to do other than help the Society in every way. There could be no progress made if any part of the body lagged behind, and Nova Scotia Mining Society was an integral part of the Institute. A committee was appointed, representing the Society and the Institute, for the purpose of formulating a policy. It was generally felt that an agreement suitable to both societies would be reached. The members are to vote on the proposal submitted by the committee.

#### The Banquet

One of the enjoyable events of the Mining Society meetings is the Annual Banquet. It was held in the Halifax Hotel and all present were unanimous that this year's Banquet excelled all former ones.

The retiring President, Mr. Geo. D. MacDougall, and Prof. Sexton gave short, practical addresses, asking the sympathy of the more experienced and prac-

tical members for the new-fledged engineers from the Technical College. Mr. C. M. O'Dell, president for the present year, and Deputy Minister T. J. Brown, both master story tellers, were at their best, and added much to the merriment of the evening. It was one of the "ne'er to be forgotten" nights, when, after a hard day's work, kindred spirits met in jovial mood." J.M.

#### NOVA SCOTIA MINES REPORT

The report on the mines of Nova Scotia for 1922 is, as usual, a tidy little volume of over 100 pages. It records operations that, on the whole, are only fairly satisfactory. The expected recovery in the coal and iron trades was badly hampered by disturbances among the workmen, due to dissatisfaction that appears to have become chronic. Gypsum production was increased from 185,934 tons in 1921 to 256,876 tons in 1922. Gold ore to the amount of 4,837 tons was milled—three times the amount of the previous year. The gradual development of the salt mine at Malagash is reflected in the increase of output from 2,606 tons in 1921 to 5,250 tons in 1922.

The provincial income of Nova Scotia is derived to a notable extent from mining. The revenue of the Mines Department during 1922 was \$548,318, the bulk of this (\$490,318) being from coal royalties. No statement of expenses of the Mines Department is given in this report; but it is only a small fraction of this amount. The mining industry is very profitable, directly as well as indirectly, to the government of Nova Scotia. It might well afford to re-invest a larger fraction of this income in services that would tend to develop still further the mineral resources of the province.

The Deputy Inspectors of Mines report briefly each on the coal mines under his supervision. The salient points about each colliery are noted, and progress during the year. A notable feature is the large amount of development and equipment of a permanent sort that has been installed in the collieries of the British Empire Steel Corporation during the year. The gradual equipping of all the principal collieries with modern wash-houses and first-aid stations is likewise recorded in these reports.

In the section devoted to metalliferous mines and quarries, most attention is paid to gold, though there was won during the year only \$16,445, from 4,837 tons of ore (uniformly called "rock" throughout the report). This gives an average recovery of only \$3.41 per ton. At the Sherbrooke Mines, 3,760 tons yielded an average of \$1.80 a ton. At the Montague Mine, 53 tons of ore yielded 106 ounces, or \$40 a ton. At the latter mine a new jigging process (wrongly called "flotation" here) is being installed, which gives some promise of success. The inspector, Mr. Thomas Beveridge, recommends that more attention be paid to large low-grade deposits of gold ore, which have not yet received the attention warranted.

Of the non-metallic minerals available in Nova Scotia, only gypsum is being mined on any considerable scale, and all of it is being exported in the raw state. The mining of rock salt is under capable and energetic management, and will probably be developed to much larger dimensions as a market is won. The report suggests that the non-metallic minerals of the province present a favourable field for private enterprise.

The report does not mention any work on oil shale during the year. Beds of shale of great potential im-

under way to make use of them might well have been recorded. There is likewise no mention of the metal-  
 output of the company.

This report in common with those of previous years, might be a good investment for the Mines Department of Nova Scotia to see that in the future reports this requisite facility for creditable appearance, as well as

### ANNUAL REPORT OF "CONSOLIDATED"

The report of the Consolidated Mining and Smelting Company of Canada, Limited, presented at the annual meeting this week, shows 1922 to have been a very satisfactory year from the operating point of view, and at least a promising year from the financial view point. Mr. James J. Warren, president of the company points out that after all current expenses and capital charges were met, there was available for addition to the reserve funds the sum of \$1,228,329. This was accomplished in spite of the very heavy capital expense involved in the building of the Sullivan mill and in the development of the Rossland mines, both of which expenditures are as yet unremunerative, as well as over \$350,000 spent on additions and alterations to the plants at Trail, most of which was used to extend the lead smelter and refinery. Mr. Warren draws attention to the burden of taxation, as "well nigh intolerable," and remarks that "fuel prices remain extortionate." He also confirms officially the arrangement whereby Consolidated will smelt Copper Mountain ore for Granby and will market the product.

Mr. Blaylock's report as general manager describes principally the smelting and refining plants. He notes that wages are still 33 1/3 per cent above the pre-war scale, supplies about 50 per cent higher and coal and coke, 100 per cent higher. In regard to the last, he notes that the coal miners are working only about half their time. The other side of the story was alluded to briefly by Mr. W. R. Wilson of Fernie at the meetings of the Canadian Institute of Mining and Metallurgy in Montreal in March when he mentioned the irregularity, and often the urgency, of orders for coke from Trail. Apparently the two managements require to "get together." Mr. Blaylock alludes briefly to the development and operation of the various plants at Trail and at the mines, which have been described from time to time in these columns. He records the highly satisfactory fact that "the metal output, which has had a steady growth during the year, has greatly exceeded that of any previous year." A highly important fact is that "the Workmen's Co-operative Committees have been in existence for three years, and have provided an ideal method of communication between the men and the management." The technical staff, as well as the workmen, of Consolidated are notable for their loyalty to the company they serve.

Mr. W. M. Archibald, manager of mines, reports a satisfactory year, both in development and in production, at the company's mines. At the Rossland mines new and important ore deposits have been discovered and developed, and are ready to supply the concentrator and smelter when they become available for use. Little was done to explore or develop the company's smaller properties, and no new properties were acquired. Little development work was done at the Sul-

livan, as the vast amount of ore already determined there is ample even for the new 1500-ton concentrator, which, by the way, is now expected to handle 2000 tons of ore a day.

Messrs. T. W. Bingay, comptroller, and W. S. Rugh, sales manager, in their brief reports, record a successful year and look forward to a better year to come. Mr. Lorne A. Campbell's report on the West Kootenay Power and Light Company concludes a very satisfactory annual statement.

### INCREASED PRODUCTION OF MAGNESITE IN UNITED STATES IN 1922,

The production of crude magnesite in the United States in 1922 was 32 per cent greater than that in 1921. It amounted to 63,487 short tons, valued at \$650,742, according to figures compiled by James M. Hill, of the United States Geological Survey. Practically all the magnesite mined in 1922 was obtained from deposits in California, though a little was mined in Washington during the latter part of the year, and some calcined magnesite was shipped from stock piles at Valley, Wash.

Figures showing the imports of magnesite since the tariff act of 1922 went into effect (September 22, 1922) have not yet been published. The imports during the part of the year prior to that date amounted to 112,159 tons, valued at \$1,757,636, as compared with 42,486 tons valued at \$592,491, in the whole of 1921.

No crude or calcined magnesite was exported in 1922. The exports of magnesite pipe and boiler coverings and other manufactures during the year amounted to 3,831, 681 pounds, valued at \$223,686.

More than 90 per cent of the domestic magnesite produced in 1922 was sold in the calcined form and brought from \$30 to \$50 a ton. A small quantity sold crude for chemical uses was priced at \$10.50 to \$12.50 a ton. The prices quoted on domestic magnesite were about \$10 a ton throughout the year.

The assurance of good prices upon the passage of the new tariff act greatly stimulated the domestic industry. Many deposits in California are being reopened, and additional equipment is being installed at calcining plants.

There is also renewed activity in the Stevens County field, Wash. All magnesite operators are optimistic as to the future of the industry.

### INDUSTRIAL ITEMS

A Gondola Car Unloader of simple and substantial design has been put on the market lately by the Link-Belt Company of Chicago. It is in the form of a revolving tippie which rotates the car after clamps have descended on its upper surface to hold it securely on the tracks, and along one side to support its weight. It can handle forty cars an hour and requires but 35 to 45 H.P. to operate. Any gondola car of standard design can be unloaded in the new mechanism. The movement of a lever controls the whole operation.

A change in personnel is announced by the Mine and Smelter Supply Co., of Denver, Colorado. Mr. Malcolm H. Carpenter has been placed in charge of the company's El Paso branch, and is succeeded in the Pacific Coast office in San Francisco by Mr. E. Shores.

# The Mining Districts

BY THE JOURNAL'S CORRESPONDENTS

## QUEBEC

**Surveys**—The staking of claims in the townships of Dufay, Montbeillard, Dasserat, Rouyn, Joannès Dufresnoy and Duprat in the counties of Abitibi and Temiscamingue has developed to such importance as to warrant surveys of all old as well as of new township lines, and of all lakes, rivers and creeks within these townships.

When notified of the necessity of more complete survey maps in the region of this new goldfield, the Survey Branch of the Department of Lands and Forests, Quebec, gave instructions for the re-survey of the base lines established by G. C. Rainboth in 1897 and by H. O'Sullivan in 1907 and of other divisional lines. With old lines well cut, the underbrush cleared, new mile posts regularly placed, and new township lines completed, the limits of any one township can not be missed.

As a claim located in the center of a township is as much as five miles from the boundary lines, a new system of tying claims to surveyed points has been inaugurated. From now on, in the townships recently surveyed, instead of having to tie a claim to a mile-post on a township line, it will only be necessary for the prospector to tie his claim to one of the numerous stations placed on all lakes and streams in the region.

In surveying the lakes, rivers and creeks within these townships, the surveyors have established well defined stations, to be shown on the survey map. In the field these stations are indicated by square or oval brass plates measuring 4 by 2½ inches, bearing the following inscription, "Dep't des Terres et Forêts-Québec-Servise des Arpentages", underneath the number of the station. In Rouyn township, where this system was inaugurated by its inventor, surveyor Jules Castonguay, the plates bear his name.

These plates are nailed on trees at frequent intervals on blazes from twelve to eighteen inches long. As many as two hundred stations have been established in Rouyn township.

The survey of Rouyn township by Mr. Castonguay and of Dasserat and Boischatel by Messrs. Jones and Malouin, which were started in January, are now completed; that of the township of Dufresnoy by Mr. P. Dutil and of Dufray and Montbeillard by Mr. A. Massé are begun but will be finished only after the break-up.

In Gaspé county, where an occurrence of copper ore has been located, the survey of three of the most important rivers, the Dartmouth, the York and the St. John, has been made and similar stations have been posted.

## NORTHERN ONTARIO

**Kirkland Lake Branch Railway.**—Chairman Geo. W. Lee, of the T. & N. O. Ry. Commission, has stated that it has been decided to proceed immediately with the construction of the Kirkland Lake branch. This branch will start at Swastika, pass through the Kirkland Lake

camp, eastward through the Crown Reserve property, with a terminus on Larder Lake. Tenders will be called for within the next two weeks, and construction work will be started without delay. Mr. Lee estimates that ten miles will be completed by next September, and that the entire line will be in operation by the first of next year. This line will serve a large and growing mining district, in which \$15,000,000 has already been expended by the various mines. In the Kirkland section there are four producing properties, with the Tough-Oakes also ready to produce. The Ar... with the very satisfactory developments at the Crown Reserve... start on one, at least, and possibly two new mills within a short time. This is the first time the T. & N. O. has built any lines to serve a mining district for twelve years, and a great deal of credit is due to the "North... construction.

**Miners' Union.**—The Forequre Miners' Union which has been dormant for several years, has suddenly come to life and presented a demand upon the managers for an increase of twenty cents an hour. For a long time the Union has had practically no organization and very few members, but according to the claims of the officials, hundreds of men are signing up, and they expect to have the camp well organized. It is understood, however, that some of the more conservative members among the miners in... which would have a big influence in retarding development in the district. If this better counsel prevails, it is probable that the operators will endeavor to meet the men. At the present time some of the mines are not deriving enough revenue from operations even to meet the payroll, but it is probable that there is likely to be a labor shortage during the summer months. Under normal conditions... claim of any increased cost of living to justify their demands, but frankly admit that they are taking advantage of the opportunity created by a shortage of men. So far nothing has been heard of a similar movement in the district.

**Cobalt.**—The annual report of the Nipissing Mine... at \$2,532,354, as compared with \$1,869,566 in the preceding year... standing the large production, the known ore reserves

decreased only 389,000 ounces and now stand at 2,615,000 ounces. A number of outside properties were examined and considerable work was done on some of them but none of the options were exercised. Dividends amounting to \$1,120,000 were paid during the year and the surplus profits as of December 31st were \$4,210,051. The report states that the mine can be relied upon for a good production during the coming year. During the month of March the company mined ore of an estimated net value of \$189,784, and shipped bullion of an estimated net value of \$173,481. There was also a production of 33,500 pounds of cobalt. The low-grade mill treated 7,193 tons and the high-grade plant 100 tons. The refinery shipped 253,783 fine ounces of bullion.

At the annual meeting of the McKinley-Darragh, the old board of directors were re-elected. It was decided that no dividend should be paid at present and the President and Manager were empowered to take what action they considered advisable regarding the acquisition of another property.

The Colonial shaft has cut the diabase-Keewatin contact at a depth of 962 feet, and crosscutting operations have already been started. It is not known just how far the crosscut will have to be extended in order to intercept the vein that is being looked for. On the Violet property of La Rose, adjoining the Colonial the shaft is down 540 feet, and it is expected that it will be completed in about five weeks. Production from this property should be resumed before the first of June.

**Porcupine**—The decreased production from the gold mines of Northern Ontario for the month of March reflects the power shortage that is being experienced in Porcupine. The value of the production was \$1,300,000 as compared with a recent record of \$2,000,000. This decline of \$700,000 in production shows how serious the power situation really is, because this loss is entirely from the Porcupine mines, the Kirkland Lake camp not being affected. It was expected that additional power would be available about the middle of April, but recently some of the worst storms in the history of this country have been experienced, which will delay the break-up. The Dome, with a considerable steam equipment, is able to treat only about 300 tons a day, while the McIntyre is down to about 100 tons.

Official advice from the Vipond state that the most encouraging discovery of recent months has been made in the 400-foot level. The vein is said to be 9 feet wide, but values are not reported.

A meeting of the shareholders of the Moneta Mine in Porcupine has been called to ratify a deal for control of the company. The prospective purchasers are English interests, who will put up the necessary money to finance operations, taking treasury stock as money is expended for work. The larger shareholders will also give an option on sufficient of their stock to ensure control.

The Porcupine-Davidson is called for tenders to sink a three-compartment incline shaft to a depth of 1000 feet. The shaft will be at an incline of 72 degrees.

Despite official statements by Hollinger officials, rumors persist that a deal for control of this property is being negotiated with English interests, and it is stated that a company with a capital of £12,000,000 is

being formed in London. Mr. Noah Timmins, President and one of the largest shareholders in the company, is in London at the present time.

At the Scottish Ontario property in Porcupine two diamond drill holes have been completed, and further drilling at greater depth will be undertaken. A third drill is to be started immediately, and it is understood that a total of about 5,000 feet will be drilled.

**Larder**—The Associated Goldfields in Larder Lake has also let a contract to sink the shaft from 500 to 750 feet. Sinking will not interfere with development work on the present levels.

**Kirkland**—The directors of the King Kirkland have negotiated a deal with the Tonopah Mining Company of Nevada for the continued development of the property, for which the Tonopah company will receive an interest. A meeting will shortly be held of the shareholder of the King Kirkland to ratify the negotiations.

## NORTHWESTERN ONTARIO

**Loon Lake Iron Range to be Drilled**—The M. A. Hanna Company, of Cleveland, O., have taken an option to explore the iron lands of the Canadian Iron Company, (generally known as the Rinaldo McConnell lands). These lands are situated at Loon Lake, 27 miles east of Port Arthur, on the Canadian Pacific Railway, and are comprised of one group of iron locations totalling about 4000 acres.

The property was examined in October last, by M. C. Lake, chief geologist of the M. A. Hanna Company, who formed a very favourable impression of the iron range as prospective producer of merchantable grades of hematite ore. The deposit is a bedded hematite from 12 to 20 feet in thickness, with a comparatively light overburden, and is traverse by the Canadian Pacific and Canadian National Railways. It lies at an elevation above Lake Superior of 450 feet and is distant about 4 miles from the head of Thunder Bay, where there is excellent deep water harbourage.

Mr. McConnell and others have done a considerable amount of diamond-drilling in this area, amounting in all to some 50 drill holes, that have disclosed large tonnages of ore, of fairly good grade, much of it being workable by open-cut operations.

Mr. M. C. Lake, geologist, accompanied by E. K. Nixon, of Hibbing, Minn., one of the M. A. Hanna Company's engineers, arrived in Port Arthur on the 12th, and are now on the property with Mr. W. J. Hunter, of the E. J. Longyear Company, of Minneapolis, Minn., who will carry out the drilling operations, with Mr. Nixon in charge for the M. A. Hanna Company's interests.

The drill and crew will arrive on the property April 17th., when drilling operations will be commenced. The drill and operators are being brought from Beardmore, on the Canadian National Railway, where they have been drilling the Leitch lands for the Bethlehem Steel Company.

The Loon Beach Hotel, at Loon, has been opened by the management for the accommodation of officials, engineers, and drilling operators.

The mines and plant of the Demerara Bauxite Company in British Guiana are now manned and it is expected that bauxite will shortly be supplied once more from these deposits.

## ALBERTA

**Alberta Coal for Ontario** — Is the coal of the Province of Alberta suitable in point of quality to meet the requirements of the consumers of the Province of Ontario?

Is it practical economically to ship coal from Alberta to the eastern Canadian market with a view to making Ontario independent of shipments from the United States?

These are the two questions engaging the attention at present of the Fuel Committee of the Canadian Senate, of the governments of the Provinces of Alberta and Ontario, of newspaper men of the two Provinces and of interested business men.

As to whether Alberta coal would be acceptable in Ontario, it was announced recently by Premier Drury in the Legislative Assembly of that Province that the matter of preventing a recurrence of the fuel shortage which has caused much misery in Eastern Canada this year was under consideration. Premier Drury said: "For some weeks this government has been in communication with the government of Alberta regarding coal. We have arranged to get a few cars down to test its fuel value. We are hoping that we can get a freight rate on the National Railways that will make the transportation of large supplies of coal feasible. After studying the situation I have more faith in a solution of the difficult problem by bringing in Alberta coal than I have either in the development of peat or the importation of eastern coal, at least for this year."

Both governmental authorities and newspapers have been actively interesting themselves in the matter. Carloads of Alberta coal have been shipped from different mines to Ontario in order that the tests may completely cover the output of the various fields of the western province. The proprietors of the "Edmonton Journal" has made a number of shipments direct to the proprietors of the "Toronto Star", who will supervise experiments independent of those officially conducted.

Howard Stutchbury, coal commissioner for Alberta, has left Edmonton for the East where he will arrange for a number of fuel demonstrations in Ottawa and Toronto in the endeavor to interest the larger manufacturers in the use of Alberta coal.

The Fuel Committee of the Senate, which is closely co-operating with the Dominion Fuel Board has asked Sir Henry Thornton, president of the Canadian National Railways, to ascertain the lowest possible freight rates that can be quoted on shipments of Alberta coals to the chief centres of Ontario. Incidentally, Dr. D. B. Dowling, who has reported on Western Canadian Coal Fields for the Canadian Geological Survey, is expected to be instructed to investigate and report as to which of the coal-bearing sections of Alberta are most likely to produce coal of a quality suitable for the necessities of the Eastern Canadian market.

**Some Mines of Alberta** — Seven car loads of coal a day, 35 tons to the car, have been coming off what is known as the Coal Branch of the Grand Trunk Pacific Railway this winter. This line in 137 miles west of Edmonton and is 56 miles in length. At Coal Spur there is a sub branch, 31 miles long, on which are situated the Mountain Park, Cadomin, and Luscar Mines which collectively employ between 1,200 and

1,300 men and turn out approximately 100 car-loads of coal a day of high-grade bituminous coal. Generally speaking, along the main branch railway the mines produce an excellent steam grade of semi-bituminous coal. Some of these mines are the Balkin, Stirling, Coal Valley, Foothills, Blackstone, and Mile 54. The Stirling and Coal Valley are "strip" mines, the former producing up to 2,000 tons a day and the latter about 600 tons. The other five aggregate some 1,800 tons a day. These seven mines have been employing roughly 900 men in recent months. At Coal Spur the Yellowhead Mine has been on fire and has not produced during the winter. It is stated that the coal resources of this field are almost unlimited and diamond drill prospecting in the bituminous area near the Cadomin Mine is in progress. The opening up of new mines in this locality is promised.

**New Mineral Tax** — The Government of the Province of Alberta estimates that its proposed new tax on mineral, gas and petroleum leases will yield a revenue of \$300,000 annually. Over fifteen million acres, now held for these rights by corporations and individuals, will be affected. The tax is to be at the rate of 3 cents an acre on mineral holdings.

A large proportion of this impost will have to be paid by the Hudson's Bay Company and the Canadian Pacific Railway Company, which hold over ten million acres of mineral rights. They obtained these lands years ago when the mineral right went with the surface. Homesteaders who obtained patents from the Crown in the early days also will be required to pay this tax for the same reason.

The government has not yet decided definitely that the three cents an acre will apply against all gas and petroleum leases.

**Docks for Alberta Coal** — Floating docks are expected to be placed at Prince Rupert B. C. for the handling of coal shipments from the the Cadomin Mine section of Alberta. It is stated that 2,000 tons a day will be provided from this field to supply the mercantile demands at the northern provincial port.

## BRITISH COLUMBIA

**The Premier Report** — Seldom has the annual report of a mining company created the interest in British Columbia as has attended the issuance recently of the report of H. A. Guess, vice president and managing Director of the Premier Gold Mining Co. Ltd., for the fiscal year ending December 31, 1922.

This is not surprising, for Mr. Guess tells very briefly and yet with transparent clarity the story of one of the most profitable of late mining enterprises on the American continent. Not only that, but the impression is left, notwithstanding the guarded and conservative phrasing, that the Premier Mine has great possibilities outside of those that are determined as a result of work done within the limited area now being developed are exploited.

What has been done in four short years could not be more forcibly set out than does the cold statistical summary of "income and profit and loss account, year 1922." The gross value of ore sold is put at \$4,782,785.43 and against that operating and miscellaneous expenses are placed at \$1,022,506.64, the earnings from mine operations being \$3,760,378.79. The whole tenor

of the... continuance of that faith in...  
 of the... to the...  
 of the... to the...

**Increase of Wages at Trail.** — The Trail Consolidated Mining & Smelting Co., which an amendment of the... subjected to criticism as a... be learned, there is no such... While... in the report that Washington... Trail, notwithstanding the fact that the Fordney tariff imposes a duty of 1 1/2 cents on refined zinc while the Canadian duty is only 1 cent. The point made is that apparently the American shipper finds the Trail rates sufficiently favourable to overcome the higher tariff against Canadian refined zinc. Attention also is drawn to the fact that there has been no change in the lead schedule, although the wage increase has as much bearing on that phase of smelter operations as on zinc.

**Cariboo** — If there is any substance to the persistent reports now circulating, the old Cariboo District of British Columbia is about to enjoy a new lease of life. A statement was made recently that £2,000,000 was being raised in London and a similar amount in Australia for the development of the placer fields of this historic section. Dredging and hydraulicking are the forms the promised activities will take and it is said that, in addition to the Cariboo, the Lillooet, Atlin and Tulameen regions are under investigation with his...

...n Cariboo operator, holds the... of Barkerville under lease... required the land on which the... population is to be moved to a... site south of the present location and higher up on the hillside in order to permit the gold content of the... to be recovered.

Barkerville's buildings are raised in order that the annual overflowing of Williams Creek, caused by spring freshets, will not damage them. The years, however, have brought decay and Mr. Hopp's enterprise has but hastened the inevitable abandonment of the one-time finance...

Gold valued at \$60,000,000, it is estimated, was taken from the... added. This, it is confidently expected, will be materially augmented by... methods.

**Mineral Exhibit for London** — Hon. William Sloan, British Columbia Minister of Mines, has returned from Ottawa, where he arranged for close co-operation between the Canada Society of Exhibitions and the Department of Mines in the preparation of a representative exhibit of provincial minerals at the Empire Exposition to be held at London next year. He also took up at the capital the matter of the coal rights claimed by settlers in the Esquimalt & Nanaimo Railway Belt on Vancouver Island and the Dominion Government pro...

The Kootenay Districts of British Columbia are pre-

paring an exhibit of minerals for display at the annual Northwest Mining Convention to be held at Spokane Wn. from the 22nd to the 26th of May next.

**Portland Canal** — The Daly Alaska, the Forty Nine, the Spider, and the Hercules are properties situated in the Salmon River section of Portland Canal, recently reported to have been bonded and upon which development work will be done this year. British interests are reported to have taken over both the Daly Alaska and the Forty Nine. The former is situated on the Alaska side of the boundary and the latter is well up the river, almost under the edge of the glacier and some three miles northwest of the Big Missouri. Belgian interests have acquired the Spider, on which the Algonquin Syndicate spent \$100,000 in development during the war years. They are reported to have abandoned it because of the discount against foreign exchange.

**Duty on Copper Rods** — The Rt. Hon. Mackenzie King, Canadian Premier, has written F. A. Starkey, secretary of the Associated Boards of Trade of Eastern B. C., that the proposal of replacing the duty on copper rods entering Canada is under consideration. The Associated Boards asked for this action at their recent convention declaring that it was necessary for the protection of the copper industry of the Province.

**Wage Agreement in Slocan** — A new wage schedule has been negotiated between the leading mine operators of the Slocan District, and the International Union Mine, Mill and Smelter Workers. It went into effect on the 1st. of April last and the wage for miners for an eight hour a day is fixed at \$5. The chief operators concerned are Clarence Cunningham, of Alamo, and the Rosebery-Surprise and Rambler-Cariboo companies. In 1920 the Silversmith, Sandon, parted company with the other mines and entered into an understanding with the One Big Union. The company is said to have decided upon a similar scale with the O.B.U.

**New Crushers for Rossland** — The installation of crushers to prepare the ore of the Rossland Mines before it is shipped to the Trail Smelter has been decided upon by the Consolidated Mining & Smelting Co. It is hoped that this additional plant will be ready for use by the time the Kimberley concentrator is completed.

**Resolution on Tax** — Silverton is the source of a resolution calling upon the provincial government to tax idle mineral claims and abandoned mine plants. Such holdings, it is stated, are held, in many cases, for speculation and should be made to pay just as is an inactive sawmill or a miner's house. The Ministers of Finance and Mines are told to wake up and "find some more reasonable and sensible method of taxing mining property."

**Ainsworth.** — The Lake Shore Mine, Ainsworth, is reported by E. J. Edwards, manager, to be looking well and it has been recommended that the property be provided with a mill of 150 tons capacity.

The Yellowstone Mine, Sheep Creek, again is in condition for operation. The concentrator has been remodelled, five new tables having been installed. Twenty men are at work in the mine driving a raise through a body of ore said to assay over \$30 a ton and the mill is working daily.

The first carload of ore to be shipped from the Emerald Mine for over three years has just gone forward to Trail. This is the property of the Iron Moun-

tain Company producing a lead-silver ore carrying a large percentage of lead.

The Florence Mine, Ainsworth, is expected to make regular shipments from now on. Two cars recently sent to the smelter gave returns of from 75 to 80 per cent lead which is a record for high-grade lead concentrate.

**Wage Agreement** The Western Canada Coal Operators' Association and the miners of District 18, U. M. W. of A. (which district comprises Eastern British Columbia and Alberta) are reported to have renewed their wage agreement for another year, the renewal dating from the 31st. March last. This was the result of a conference held at Calgary early last month.

It is interesting to note in this connection that the Hon. James Murdock, Dominion Minister of Labour, has replied to the Associated Boards of Trade of Eastern B.C. that, in view of this settlement of the wage question, it will be impossible for the federal department of labour to do anything definite towards probing the alleged high cost of western coal production. The Associated Boards passed a resolution at a recent convention held at Trail declaring that the excessive cost of coal and coke was proving a handicap to industry, that the policy of Alberta coal miners was dictated by United States labour leaders, and that it was important that official cognizance of the situation should be taken by the ordering of a thorough investigation.

**Jingle Pot Mine** — The new "Jingle Pot" or "Grant's Mine", which has been opened up near Nanaimo, gives promise of becoming a considerable producer. Surface plant, including railway facilities, wharf and bunkers on the waterfront close to the City of Nanaimo, was taken over from the old and now abandoned "Jingle Pot." It is in good shape and quite adequate to handle the output of the new workings. The hoisting slope has been driven to a fine five-foot seam of coal and as soon as places can be opened up the property will be shipping continuously and in substantial quantities.

**Coal Miners Punished** — Since the disaster of last February in No. 4 Mine, Canadian Collieries (D) Ltd., Cumberland B.C., there have been a number of prosecutions for infractions of the "Coal Regulation Act" on the part of underground workers. In one case Mike Bulatovich, a Montenegrin miner, was fined \$10 and costs for taking into the mine a Wolf safety lamp that had not previously been examined by a competent person. The accused said he had taken the lamp in to the mine by mistake and on discovering the mistake had put it out. A Chinaman, How On, was sent to jail for thirty days for taking underground a key to an electric safety lamp. He stated that he had picked it up on the street and had forgotten that it was in his possession. It is understood that other prosecutions under the Act are to be called shortly.

## EXPLOSIVES IN UNITED STATES IN 1922

The quantity of explosives sold in the United States during the calendar year 1922 was greater by more than 16 per cent than the amount sold in 1921. Report received by the Bureau of Mines, Washington, show that the total sales amounted to 431,772,077 pounds as compared with 372,107,503 pounds the year before. Of the total amount sold 178,866,225 pounds was black

blasting powder, 209,476,084 pounds high explosives other than permissible explosives, and 43,429,768 pounds permissible explosives. Permissible explosives are those that, because of having passed certain tests prescribed by the Bureau of Mines, are considered reasonably safe for use in gaseous and dusty coal mines.

The coal-mining industry is always the largest consumer of black powder and permissible explosives, the consumption usually comprising about 85 per cent of the entire amount manufactured. In 1922 the coal mines used 6,190,478 kegs or 154,761,950 pounds of black powder, as compared with 5,613,435 kegs or 140,335,875 pounds in 1921. In 1922 the coal mines used 25,497,758 pounds of high explosives other than permissibles as against 34,231,542 pounds used 1921. The coal-mining industry in 1922 used 43,429,768 pounds of permissible explosives compared with 38,055,650 pounds of permissibles used in 1921.

Metal mining and all other mining operations (excluding coal) in 1922 used 167,700 kegs or 4,192,500 pounds of black powder as compared with 184,792 kegs or 4,619,800 pounds used in 1921. In 1922 the same mining industries used 78,074,489 pounds of high explosives other than permissibles and 1,452,500 pounds of permissible explosives as against 50,977,366 pounds of high explosives and 881,710 pounds of permissible used in 1921.

The coal reserve of Spitzbergen is estimated to be 10,000 million tons. The production in 1922 was 210,000 tons, and was due mainly to American enterprise. The mining community comprises about 500 persons.

The British China clay production in 1922 was 745,000 tons, against 350,000 tons in 1921, and 900,000 tons in 1912, a record year. About 250,000 tons annually is shipped to the United States.

## PURCHASE OF GOLD ORES

The attention of prospectors and others is drawn to the provision in the Mining Act of Ontario authorizing the Department of Mines to purchase parcels of gold ore taken out by prospectors and others in developing or working mining claims. Arrangements have been made by which such parcels of gold ore, whether large or small, will be accepted by the Temiskaming Testing Laboratories at Cobalt, and paid for according to the schedule provided for the purpose. The Laboratories are operated under the auspices of the Department of Mines.

This offers a first class opportunity for testing the value of ores on a large scale, and also of turning ore of good quality into money for carrying on further development work. By special arrangements, on less than carload lots, freight rates on the T. & N. O. Railway are reduced 50 per cent.

The Laboratories are also equipped for working out the best methods of treatment for gold or silver ores of a refractory or unusual character.

Full information as to treatment charges, schedule of payments, etc., can be obtained from the undersigned, or from A. A. Cole, Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

THOS. W. GIBSON,

Deputy Minister of Mines.

Toronto, 12th March, 1923

### THE "CUB"--A LINK-BELT LOADER--\$790.00

#### FEATURES

Simplicity of design.  
Length of conveyor, 21 ft.  
Substantial construction—weighs about twice as much as some machines of this type.  
18" wide belt, giving large carrying capacity.  
Belt guaranteed against cutting or fraying.  
Wide loading hopper at foot of conveyor is hinged easily and quickly opened.  
Requires little power—2 H.P. motor, 2 or 3 phase, 60 cycle, A. C.

**H**ERE'S a thousand-dollar Link-Belt Portable Belt Conveyor at our new low price—\$790.00. It is one of our standard types, built to the high Link-Belt standard. It is guaranteed.

Increased production, due to our large volume of sales, has made this low price possible.

Even if you load only a small quantity of material—at intervals—can you afford to pass up an opportunity like this? Fill out and return the coupon.

PROVINCE OF ONTARIO

# Minerals

DEPARTMENT OF MINES

HON H. MILLS, Minister of Mines

## Mineral Areas.

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favorable for the occurrence of minerals, 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver mines of Cobalt occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

## Economic Minerals.

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario:—actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluor-spar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, portland cement, brick and tile, meet every demand.

## Mineral Production.

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1921 to be worth \$48,128,387, of which the metallic production was \$27,574,202.

The following figures show the rapid growth of Ontario's mineral industry by five-year periods since 1891:

| Year.          | Value.      | Year.          | Value.       |
|----------------|-------------|----------------|--------------|
| 1891 . . . . . | \$4,705,672 | 1906 . . . . . | \$22,388,383 |
| 1896 . . . . . | 5,235,003   | 1911 . . . . . | 41,976,797   |
| 1901 . . . . . | 11,831,086  | 1916 . . . . . | 65,303,822   |

## Dividends.

Dividends and bonuses paid to the end of 1921 amounted to \$23,140,734 for gold mining companies, and \$84,388,185 for silver mining companies or a total of \$107,528,919.

## Mining Regulations.

A miner's license costs \$5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of \$2.50 or \$3.00 per acre, depending on location in unsurveyed or surveyed territory.

## Assay Office.

The Provincial Assay Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

## Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

## Serving the Mining Engineer

The usefulness of a bank can only be judged by the advantages its service affords you.

The Imperial Bank, having over 200 branches distributed throughout the length and breadth of the Dominion—some of them located at remote points—is in a position to serve the mining engineer in all things financial. You will find this Bank's service always near at hand.

At all branches of this Bank the same courteous service is afforded to depositors whether their account be large or small.

## THE INSTITUTE AND THE PUBLIC

The Canadian Institute of Mining and Metallurgy owes to itself, to the mineral industry of Canada and to the Canadian public a duty that at present it is making no serious attempt to perform.

In recent weeks we have discussed briefly in these columns the present lack of an effective contact between the mining engineers of this country, as representing their industry, and the population at large, whose interests the mining industry is designed to serve. We have alluded to the absurd misconceptions that comprise the average Canadian's ideas of the mineral industry of his country, and have pointed out some possible means whereby those engaged professionally in the industry can, by word and deed, help to correct these false impressions. We have likewise adverted to the fact that a great deal of good can be done by displacing in the public press a large part of the present mining "news" with authentic information, just as interesting and readable, provided by a publicity officer in the Department of Mines at Ottawa.

Last month we had a demonstration of the genuine influence of which the Canadian Institute of Mining and Metallurgy is capable, when its energies are directed into a channel big enough to hold them. The symposium on fuel supply, presented at a critical time, not only served to collect authentic and comprehensive data on the subject, but also proved to be a crystallizing force for public opinion. By means of the papers presented, the discussion that followed and the widespread publicity given the meetings in the public press, all Canada knew, almost before the meetings had been concluded, that cheap transportation of Alberta coal is at the heart of our problem and that the substitution of coke for anthracite is likely to ensure at all times an adequate supply of domestic fuel in the "acute fuel area". The Institute did the country a notable service at the recent annual meeting.

A similar opportunity, on a grander scale, awaits the Institutes' attention now. The eyes of the world are turned to Canada as the favoured land of the day. Our mining industry particularly is attracting attention. A movement of capital in large amounts to our mining camps, established and in embryo, has already commenced. It is possible, and indeed probable, that this inflow of the capital required to exploit our mineral areas will reach vast proportions. Meantime Cana-

dian capital in amounts very creditable to our young country and our still younger mining industry is finding its way to mine and prospect.

Where does the Institute come in as a factor in this development? At present, we fear, it does not cut much of a figure. This is not from lack of ability or for lack of opportunity, but merely from neglect to delineate clearly a self-appointed task and then to bend its back to the work. Let us consider squarely a few random points in this connection.

Mining investors with large sums of money to spend are rapidly finding, and making, opportunities for putting their funds into the "game" in Canada. They are well able to look after themselves, in every way. They are a gregarious breed, and now that Canada is the vogue in mining, we shall have an increasing number of them, principally from Great Britain and the United States. Their exploring and mining operations have already provided the reason for the growing popular interest in the mineral industry, which we may expect soon to assume boom proportions.

It is this popular interest in mining for which the Institute can, and should, assume a certain measure of responsibility. A boom period invariably provides a golden opportunity for the vendor of useless mining claims, the fake promoter, the stock-jobber, the manipulator of stocks, and the whole light-fingered breed. Preventive laws can at best merely palliate the evil. A certain proportion of sheep are sure to be shorn. Those susceptible of protection against fraud can best be served if they are offered the truth about the mineral industry along with the falsehood that is bound to circulate in some degree. We hold that, if the truth is made as readily available as is falsehood, it will displace it to a very large extent.

This is one point, among many, to which the Institute can bend its energies with benefit to itself, the profession, the mineral industry and the country. The headquarters can duplicate, not once but many times, the success of last month's effort. By adopting similar means the branches in our various mineral districts can collect similarly authentic and authoritative data, each on its own resources and its local problems. The means are available, for the asking, to circulate such information broadcast throughout Canada.

The Institute set a mark for itself in its recent annual meeting. Its labours on behalf of the industry and the Canadian public have borne fruit already. We can repeat this service to ourselves and to our country

by tackling one after another of the serious public problems that confront us. Let us measure up to the standard we have set.

### A PICTURE OF CANADA

Canada's future is bound up inextricably with the production of mineral wealth. This has been realized fully as yet only by a handful of Canadians. A larger number have a dim comprehension of this vital phase of the problem of our national development. Most Canadians still fail to grasp its true significance.

Dr. Corless has added to his already notable service as a public proponent of our mineral industry. On Monday of last week he delivered before the Canadian Club in Toronto the address of which we print the first instalment today. In it he has painted in bold strokes the physiographic and geological map of Canada. He shows the great interior continental plain, flanked on either side by mountains, terminated abruptly in Ontario and Quebec near their southern borders by the pre-Cambrian shield, and squeezed to rapidly diminishing dimensions northward from the international boundary in our prairie provinces. It is upon this small share of the fertile interior plain that Canada's world importance as an agricultural country must rest.

The remainder of our country — by far its larger part — is composed of regions of hill, lake and mountain, interspersed with fertile valleys, and an occasional feature like the Great Clay Belt of northern Ontario and Quebec. Settlers in these scattered areas must look to local markets for the profitable sale of their produce. The mineral industry will form the most secure, as well as the most profitable, basis for such a market. Dr. Corless shows by citation of fact and by logical deduction, that we are assured of a mineral industry adequate to this need. It remains for us all to help develop it each in the way suited to his ability and his opportunity.

### THE "BLUE SKY" BILL IN ONTARIO

"The only freedom I care about is the freedom to do right; the freedom to do wrong I am ready to part with on the cheapest terms to anyone who will take it off me."

So wrote Huxley at a time when scientific truth had commenced its struggle for power, but while error still held sway in the land. His conclusion can be applied with equal aptitude to the movement now under way on this continent to protect the helpless and the unwary from the schemes of the dishonest promoter and stock-jobber.

The present government of Ontario has made an honest and straightforward attempt to put on the statute books a so-called "blue sky law," designed with an object that every honest citizen will approve. To

such a law there can be made objection only by two classes of persons, — those whose illicit transactions would be thus curtailed, and those who consider that the law in question is not the best means of effecting the object in view. We can afford to ignore those who are willing to "let well enough alone"; for in this case they either are wilfully blind to the need of adequate policing of public financial operations, or they have neglected to study the matter and have passed judgment without having first informed themselves. Consequently the task of those advocating this protective measure is reduced to convincing those interested that the present bill is the proper expedient. As the measure is non-controversial in the way of party politics, we can reasonably hope that the pending provincial election will not interfere with its transference to the statute books, either before or after the election.

The present laws in Ontario dealing with the public sale of stock have been proved quite inadequate for the effective administration of justice. This has been proved time and again during recent years, when conviction or even legal action for fraud have been prevented by the many "loop-holes" of which those guilty of fraud have taken advantage. The present bill is designed to stop these gaps in the law and to provide some simple additional measures of precaution. It proposes, in brief, to force every promoter, broker and salesman to put his cards on the table, so that the prospective buyer of stock may judge fairly their value. It imposes no restriction on promotions other than this, and offers no guarantee to the investor. It merely insists, throughout its various sections, that the truth be told and that falsehood be excluded. Surely this is a worthy object, and without danger to any honest man.

The bill, as presented at its second reading on April 6th, covers fifteen pages, most of this space being occupied by items necessary to ensure proper legal interpretation. The gist of the bill is that every issuer of securities shall submit to the scrutiny of a commissioner of securities a statement, verified by competent business and technical authorities, describing the physical basis of the issue of stock and the method and conditions of issuance. It provides likewise that every stock salesman shall be licensed, and shall give to every buyer of stock a prospectus setting forth plainly the essential information contained in the statement filed. The statement is to include such information as the purposes to which the proceeds of the stock issue is to be applied; the amount of vendor stock issued; the capital liabilities of the company; the interest of each director in the promotion itself or in any property it is proposed to acquire. It protects the reporting engineer from garbled reports by specifying that he be quoted verbatim. It also proposes that advertisements in newspapers and other periodicals shall be subject to the same scrutiny and regulation as are prospectures.

The bill, while designed as a general measure of protection against fraudulent issues of stock, takes special cognizance of mine promotions. The country needs this protection now and will need it more during the mining boom that is pending. We see in it nothing essential to which we can take exception, and much that will help improve the status of the mining industry. In one place it requires a report from a "registered professional mining engineer." Many mining engineers object to registration in the provincial associations, but all are registered in the Canadian Institute of Mining and Metallurgy, and no doubt this latter registration comes under the meaning of this clause. The bill deserves the support of the whole Canadian mining fraternity.

In evidence given recently before the Senate committee on fuel a gasworks manager stated that the output of coke from his plants was relatively small, due to the comparatively small demand for gas under present conditions. This draws attention to the inherent weakness of the old-time gasworks. It can supply gas only at a price that cannot compete with solid fuels. It makes good gas and good coke, but it cannot make either so cheaply as does the modern by-product coke oven plant nor does it make so good a recovery of by-products. The time is now at hand when the by-product plant will displace entirely the old style gas plant, providing coke in competition with anthracite coal, gas at a rate very much below its present cost, and by-products in such abundance as to stimulate our chemical industries and the use of artificial fertilizers in intensive farming. The price of gas will have to be reduced to a point where it can be used for heating, as is fuel oil at present; and this lower price will induce a domestic consumption much more extensive than at present.

The expansion of our mineral industry depends in the first instance upon the efforts of the prospector. He should be preceded, as well as accompanied in his search, by the geologist, who can best mark out for him the broad lines of his search and interpret what would otherwise be puzzling bits of evidence. We give today some hints to prospectors from Mr. George Clothier, resident government engineer in charge of the Portland Canal district of British Columbia. Hints from public servants like Mr. Clothier have proved to be so prolific of practical results that there is no doubt many of the prospectors who will swarn round the Premier Mine will follow his advice. Every effort such as this, that tends to lessen a useless concentration of men round proved areas is effort well expended. To point out to prospectors promising areas on the outskirts, and beyond, is a genuine public service.

The market for nickel has revived with wonderful rapidity since the dull days of the recent industrial depression. It is truly remarkable that, with the former outlet by way of armour-plate and munitions of war virtually blocked, the industrial use should have been increased to their present extent. This has not been done without determined effort, judiciously directed, on the part of the staffs of the three nickel companies. A large part of the credit for this revival must be placed to the credit of research work. Particularly is this the case with the British America Nickel Corporation, the latest of the three companies to resume active operations. When the work of this company's metallurgists is recorded publicly, it will provide an intensely interesting story — a story such as will stimulate similar faithful endeavour among those with similarly hard problems to solve. We are glad to see this research work about to be translated into commercial activity at Nickelton and Deschenes.

As we go to press, word comes of the sudden and shameful outbreak of lawlessness in the mining camps of Thetford. Evidently Sydney has no monopoly of Canadian Bolsheviks.

## DISPARAGERS

### A Ditty of Indictment

Let us with a cheerful mind  
Cherish hopes when so inclined:  
Disregard the croaking gent  
Who insists the world's hell-bent.

\* \* \*

When Porcupine first came to view  
It was admired by very few;  
The greatest experts looked askance  
And scarce vouchsafed a second glance.  
And South Lorrain, in earlier days,  
Received no whit of expert praise.  
In Cobalt, too, the like occurred—  
Few savants spoke a cheering word.  
So, likewise, out in far B. C.,  
Portland Canal was marked N. G.  
Well, as the vulgar minstrel sings,  
Look now upon the bleeding things!  
Discredited and damned by those  
Who must preserve their cautious pose,  
They yet survive and blossom forth  
To attest the glory of the North.

\* \* \*

Good it is to cherish hope  
When it's based on reasoned dope.  
Even Labrador may be  
Added to our galaxy!

### Editor's Note:—

Really, we must call a halt—  
Take those last two lines with salt!

# Some of Canada's National Problems\*

AND THEIR PHYSIOGRAPHIC CAUSE

By C. V. CORLESS\*\*

## Introductory

Not only is man a denizen of the earth; he derives from it his physical origin and sustenance. But the course of his evolution has been such that, for his food and raiment, he finds himself dependent on pre-existing forms of life. Only all-essential air and water and minute quantities of minerals is he able, for his subsistence, to take directly from the hand of his mother earth.

Originally, therefore, man was, from sheer necessity, a hunter for the materials of his food and clothing. Only later, through pressure of increasing numbers, did he learn to domesticate and pasture animals, and finally to till the soil, thus lessening the precariousness of his existence. The pangs of hunger and the impulse to propagate his species — those primitive urges that constitute the greatest and most universal ultimate stimuli to war, and to progress in peace — are the primary forces driving him to seek out and develop lands suitable for cultivation. Little, therefore, is it to be wondered at, that man's first thought regarding any part of the earth is concerned with its surface, soil and climate, since these determine its suitability for cultivation. Food and raiment, the conditions of our continued existence, must forever receive our first attention.

## Reasons for Emphasis on Agriculture

These considerations suggest the primary reason why, so far, we have looked almost exclusively to Canada's farming lands as the greatest potential source of her future wealth. But a strong secondary influence has seriously affected our opinion of the relative extent and importance of Canada's agricultural area. The greatest store of agricultural wealth yet developed on our planet is the central plain of North America, of which Canada's three most extensive farming areas are northward extensions, viz., Southern Quebec, Southern Ontario, and the cultivable parts of the Prairie Provinces. It was only natural that, at first, we should regard our relatively small parts of this plain as if they had expansiveness similar to the great body of it south of the international boundary.

## Limitations to Agriculture; The Laurentian Highland

But, aside from the limiting effect of climate, as we go northward there is a very important factor that must be carefully considered before the prevailing view of the vast extent of Canada's total agricultural area can be accepted without qualification. The great, northward-expanding, funnel-shaped, agricultural plain of North America, flanked by the Appalachian Highland on the east and the Pacific Highland on the west, is, as it were, nearly plugged to the northward by the greatest of Canada's physical features, the so-called Laurentian Highland, which occupies well over one-half the area of the entire country.

Those eastern and western bulwarks or sea-walls of the North American Continent, as we go northward, diverge so rapidly that, measured along the 49th parallel, the interval between them is more than 2,000 miles. Of this interval, more than 60% at this latitude is blocked by the Laurentian Highland, which thus narrows the Canadian section of the central plain at Winnipeg to about 800 miles. Nor does the narrowing end here. Near the northern end of Lake Winnipeg the outer margin of the Laurentian Highland turns sharply westward, crosses Saskatchewan and, turning northwestward, even nips a corner of 2,000 square miles off Alberta, thus further lessening the width of the central plain, measured along the 60th parallel (the boundary between the Prairie Provinces and the North West Territories), to about 400 miles. North of this parallel, the central plain narrows still further to 200 or 300 miles, where it becomes little more than the mere valley of MacKenzie River. Of this vast central plain of the continent, the greatest storehouse of farming wealth in the world, this enormous Laurentian plug leaves to Canada only the southern tip of Ontario, with which you are so familiar, having an area of but 35 or 40 thousand square miles; a similar area comprised of southern Quebec and the eastern corner of Ontario, separated from the Ontarian tip by a southward spur of the Laurentian into New York State; and the tapered western area just outlined chiefly within the Prairie Provinces.

It is this vast Laurentian Highland, nearly equal in area to 60 percent of Canada's mainland; so little known; so little understood; so generally ignored; and yet, because of its geological history and structure, its geographical position, and its great area, of so vital importance in our national development; to which I wish to invite your attention for a few minutes.

## Extent of the Laurentian Highland

When you take your summer outing in Muskoka, you enter this highland about 75 miles north of Toronto. If you go to Winnipeg, you are travelling over it from Orillia to within a few miles of your destination. When you are in Muskoka, it stretches north-easterly from where you are located for more than a thousand miles, and north-westerly for more than two thousand miles. If you take your summer holiday by a sail down lake, rivers, and gulf, to Belle Isle Strait, the Laurentian Highland is never more than a few miles from the north shore past which you are gliding; you cross a spur from it into New York State, where the St. Lawrence breaks through forming the beautiful Thousand Islands; you are only thirty miles from its southern rim at Montreal; it steadily approaches the shore as you continue down the river until, from a point a few miles east of Quebec City, it forms the bold and somewhat forbidding shoreline of river and gulf for the remaining eight hundred miles. To your right as you leave Cornwall, Montreal and Quebec behind, lie, first, the agricultural plain of Quebec,

\* Address to The Canadian Club, Toronto, April 16th, 1923.

\*\* Director and Manager of the Mond Nickel Company.

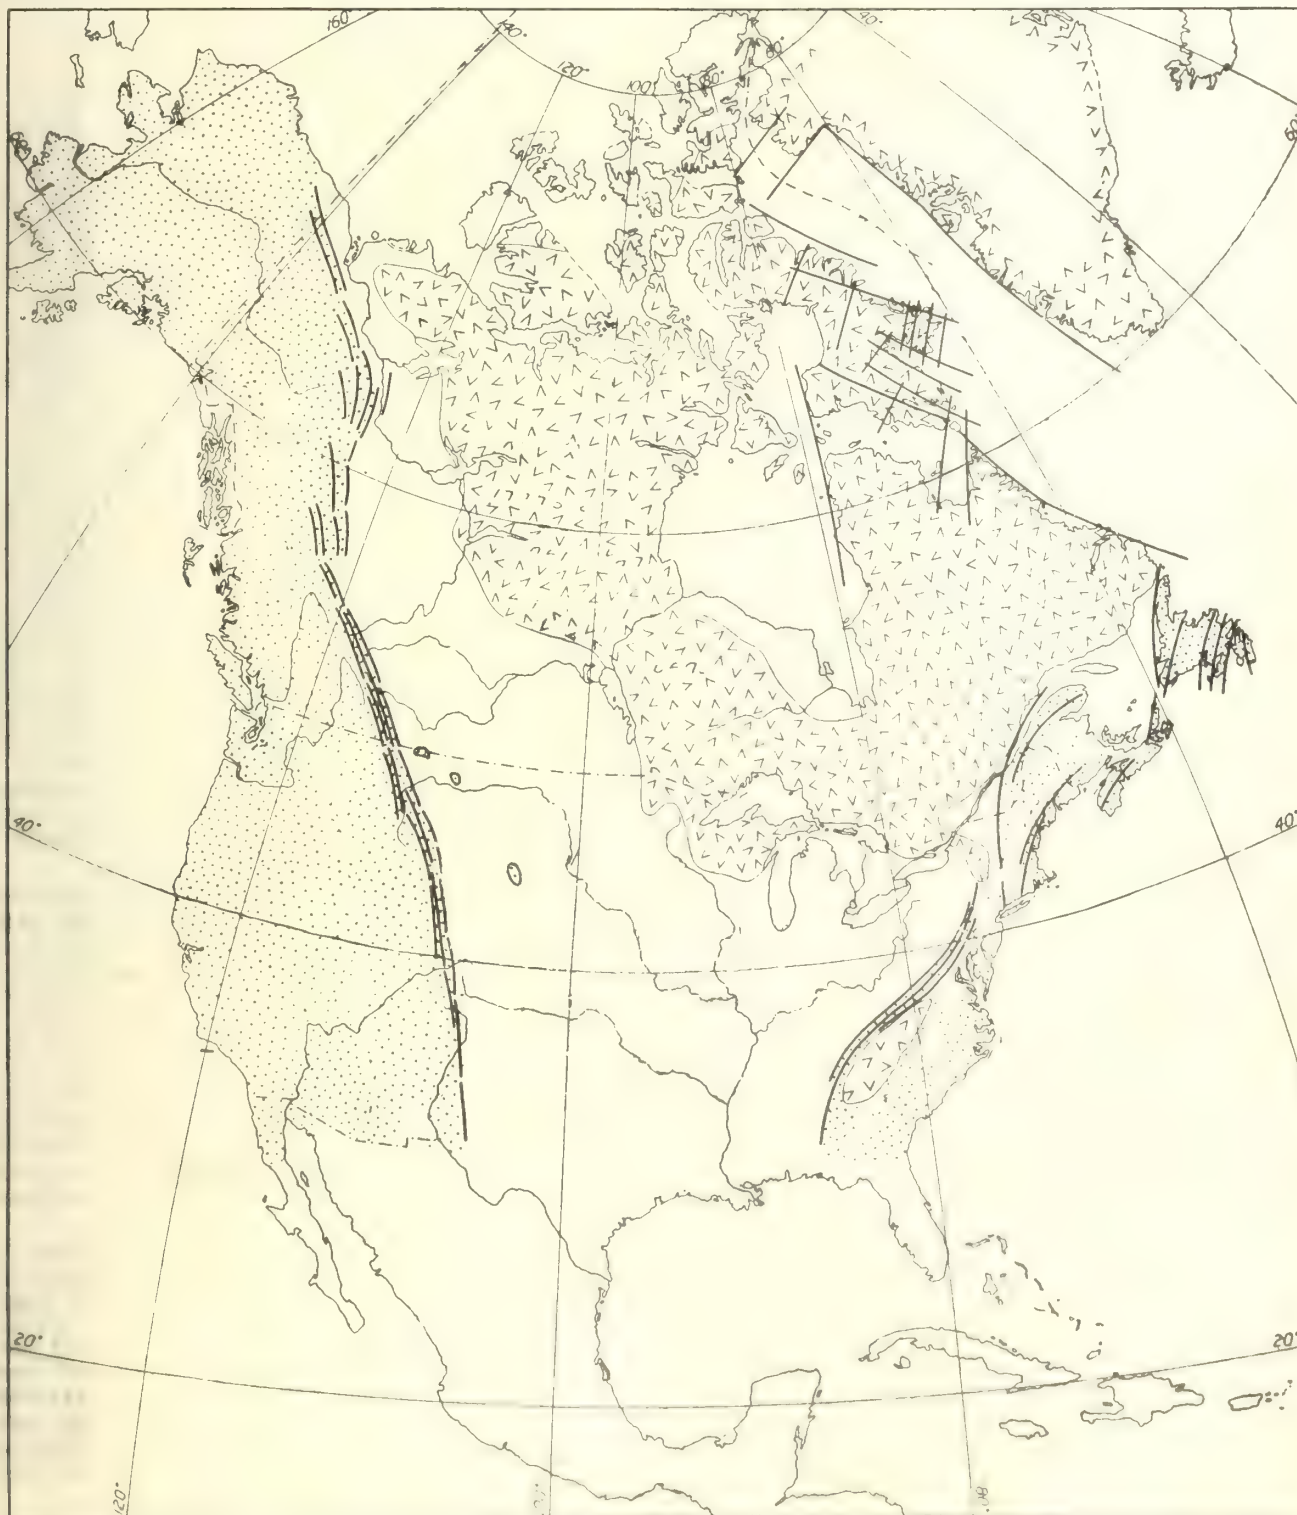

noted for its fertility and for the thrift and contentment of its people; and next, the Acadian Highland, the Canadian extension of the Appalachian Highland, which spreads out into Gaspé Peninsula and the three Maritime Provinces, before disappearing under the waters of the Gulf. This whole area to your right, including plain, peninsula, and provinces by the sea, totals only about two and one-half percent of Canada; while to your left you were passing Canada's greatest physical feature, spread out over more than twenty

times this area, more than one-half the surface of the entire country, or over an area equal to two-thirds of that of the great country to the south of us.

#### **The Laurentian Highland—the Source of National Problems**

This vast Laurentian Highland, stretching from the St. Lawrence and Atlantic westward to Great Bear, Great Slave, Athabasca, and Winnipeg Lakes; extending from Superior and Huron northward to well within the Arctic Circle; and surrounding that great North-

The above sketch map indicates the general physiographic and geological features of this continent. The fertile interior plain covers only the southwestern peninsula of Ontario and the upper St. Lawrence valley in eastern Canada. In the west it includes Alberta, the southern half of Saskatchewan and a corner of Manitoba. It is flanked by mountains on the east and west. The northern half of the continent is occupied mainly by the pre-Cambrian "shield" round Hudson's Bay. Within this vast area the products of the forest and mine will always be the principal inducement to human habitation.

an Mediterranean Hudson Bay, which has more than 150,000 square miles of surface; is the physiographical cause of many, if not most, of Canada's greatest national problems. Nor are these problems merely geographical; they are also economic, sociological and political. This great physical feature separates and isolates Canada's western and eastern agricultural populations; it hampers their efforts and lessens the value of their produce; it hinders the unification of ideas; it thus gives rise to divergent political views; it prevents easy assimilation of in-coming peoples; it has baffled our understanding to such an extent that our failure to grasp its meaning, to grapple effectively with it, to seize its rare opportunities, to develop it in place of ignoring or exploiting it, has been and is one of the greatest causes of our steady loss of population; it is also the cause of our fuel problem, at present so urgently demanding solution; and it is, at bottom, the cause of our great railway problem, the solution of which must, in great part, become interdependent with the solution of the fuel problem. From Winnipeg, almost on the contact of prairie and highland, to Toronto, Montreal and Quebec, rail distances of twelve to fifteen hundred miles, our three transcontinental lines traverse this almost unpeopled area. Enormous in extent, most ancient and complex in geological formation, denuded of most of its soil by recent glaciation, this pre-Cambrian Shield, as it is conveniently called in order to remind us of its great geological age, gives rise to a series of profoundly difficult national problems that challenge the intelligence, courage and enterprise of all Canadians who are deeply interested in the development of their country. It is not more rhetorical use of hyperbole to say: If you wish to understand Canada and Canadian problems, study the Laurentian Highland.

### Need of Study of Pre-Cambrian Shield

But this attentive study of Canada's greatest physical feature is precisely the duty that most Canadians have left undone. To our Dominion Government, it has chiefly been a vast barrier, a wilderness to be traversed, rather than opened up, in order to reach and develop western plain and plateau. Our Provincial Governments, much as we appreciate the relatively little they have done, have given scant attention to the needs and resources of 90 percent of their provincial areas, their interest centering rather in taxing than in developing their portions of it. Even our school text-books almost ignore it, dismissing their accounts of more than half of our country with a few brief paragraphs. A few Canadians enter it for a short distance for a summer's outing on one of its myriad lakes, or spend a few days in enjoyment of its wonderful sport with rod or gun. A few more reluctantly traverse its southern fringe on their way to western plain or mountain. And still others confine their study of this great area to the promoter's advertising, making wild plunges in the bogs of misinformation which some of these arm-chair pioneers deliberately create. The great mass of our more intelligent fellow-Canadians know little of, and care even less for, this greater part of their native country. But there are a few others, thank Heaven, having still the red blood and pioneering instinct of the ancient Saxon and Viking, yes, even of our fathers and grand-fathers, coarsing in their veins — courageous and enterprising explorers, geologists, engineers, prospectors,

lumbermen, miners, and other real pioneers — who, undaunted by difficulties, are exploring and deeply studying such parts of this vast area as they can reach and who, within the past quarter century, have already brought to light dazzling visions of undreamed-of wealth in its forests and lying hidden beneath its surface. The period in which we are living is truly the soft age of crowded cities, paved roads, costly limousines, moving pictures; love of ease with corresponding loss of initiative and enterprise; resulting too frequently in soup-kitchens and unemployment doles; and all this, with a vast territory of unlimited opportunity lying undeveloped at our doors.

### Distribution among the Provinces

Let us begin our brief study of the pre-Cambrian Shield, which is spread out over 2,000,000 square miles, by glancing at its distribution among the provinces and territories of Canada. For our purposes, approximations, which stick easily in memory, will be more useful than more exact figures, quickly forgotten.

A small part of the Shield is exposed in some of the eastern Arctic Islands. Of the mainland portion, roughly resembling a great horse-shoe, about one-third fills more than ninety percent of Quebec extending from Hudson Strait practically to the Ottawa and St. Lawrence Rivers. A little more than one-third of the entire pre-Cambrian Shield occupies most of the North West Territories; extending from the northern boundary of the Prairie Provinces, practically to the Polar waters; stretching from Hudson Bay almost to the valley of MacKenzie River; and half surrounding those large north-western glacial lakes, Great Bear and Great Slave, each of which is about 50 percent larger than your own Lake Ontario. Each of these prongs of the vast horse-shoe, the Labrador or north-eastern prong, and the MacKenzie-Keewatin or north-western prong, expands northward to the enormous width of over 1,000 miles.

The remainder of the pre-Cambrian Shield, well over 500,000 square miles in area, being nearly of the same area as British Columbia and Yukon Territory together, is divided about equally between Ontario and the three Prairie Provinces. It fills most of Ontario and Manitoba, which should hardly be called a Prairie Province. It occupies the northern one-third of Saskatchewan; and it surrounds Lake Athabasca, thus filling about 2,000 square miles of the north-easterly corner of Alberta. This lake, which is as long as Lake Ontario, will probably at some future time be an important connecting link in the transportation outlet, via Huson Bay, of Northern Alberta and the Peace River district of British Columbia.

Thus this vast physical feature, roughly equal in area to the entire Pacific Highland or Rocky mountain Plateau from Panama to Alaska, and ten percent larger than India which supports two-thirds of the population of the whole British Empire, directly and profoundly affects every province of the Dominion east of the Rocky Mountains, except the three Maritime Provinces, which have a combined area of only one-fortieth of the pre-Cambrian Shield; and indirectly affects the remainder of Canada, perhaps equally profoundly.

### Climate of the Pre-Cambrian Shield

Though the climate of the Laurentian Highland is fairly well known, a brief summary of climatic conditions may not be out of place. The latitude of this

great area is the same as that of the body of Europe, if we omit the Iberian, Italian and Balkan Peninsulas. The southern part, including most of Labrador, is, relative to the equator, in a similar position to France, Germany, the old Austrian Empire, and Southern Russia; the northern part is in a corresponding position to Scandinavia, Finland and northern Russia. But, owing partly to the configuration of the Atlantic-Arctic Ocean; partly to the presence of an extensive archipelago of large islands off the northern coast-line of North America; and partly to the practical absence of such obstructions off the northern coast-line of Eur-Asia; the climate of Europe is softened by the ameliorating influence of the broad drift of equatorial water, known as the Gulf Stream: whereas the climate of the Laurentian Highland is chilled by the cold blasts that sweep over the great expanse of snow and ice covering or held among those northern islands; or, by the damp and penetrating winds that sweep across the broad current of icy water drifting southward through Davis Strait, washing the coast of Labrador, and even carrying part of its load of icebergs through Belle Isle Strait and into the Gulf of St. Lawrence. This climatic contrast between similar latitudes in Europe and Canada is the classic example of the overpowering influence of air,—and ocean,—currents over mere latitude; or, to generalise more broadly, of mobility over fixity. An easy inference from these conditions, borne out by the facts, is that generally precipitation over the entire pre-Cambrian area will be light as compared with similar latitudes in Europe. As is to be expected it increases somewhat as the coast and larger lakes are neared. But no vast mountain-wall intervenes, as between southern British Columbia and southern Alberta to increase precipitation on one side and lessen it on the other. Over the pre-Cambrian area as a whole precipitation is remarkably uniform. There is no desert spot due solely to lack of moisture. Nor is there any extended part afflicted with nearly continuous cloudiness and superabundance of moisture. A high percentage of clear sky and sunshine throughout the summer season is the general rule over the entire area that has been explored.

### Geology of the Shield

But the complete climatic picture is not quite so grim and hard as this first rough outline sketch would make it appear. Climate is greatly influenced by elevation as well as by wind water, and latitude. It is a surprising fact that this vast area, though subject to the adverse climatic influences outlined, has probably less permanent snow than is to be found above the snowline within the torrid zone. Light precipitation and remarkably uniform and low average elevation are the explanation. Much of the area sloping to Hudson Bay is less than one thousand feet above sea level and the greater part of the remainder is under two thousand feet. Only one small area is of really mountainous altitude, the Nachvak Mountains of north-eastern Labrador, said by Dr. Coleman to reach the very moderate elevation of six thousand feet. This practical absence of permanent snow and ice, during the present geological epoch, is of great economic importance. It is probable that, but for this condition, very little, if any, of Canada east of the Rocky Mountains could successfully grow either cereals or fruits. In view of this uniformly low elevation, the term Laurentian Highland is somewhat mis-leading, the more

significant geological appellation pre-Cambrian Shield, being preferable.

The science of geology is the most essential key to a proper economic understanding of the pre-Cambrian Shield. Perhaps of no other equivalent area on our planet is this statement equally true. We must therefore by a few bold strokes, try to convey, however inadequately, a broad outline of the most crucial geological facts concerning this great area.

The remarkably and uniformly low elevation of so vast an area; the bare, smoothed and rounded hills of rock, many with striated surfaces, comprising most of the present surface; the myriads of crystal lakes, and the innumerable peat-bogs and muskegs, scattered indiscriminately everywhere; the indefinite complicated drainage, through numberless streamlets, creeks and rivers, tumbling without plan or system over countless rapids, cascades and falls, rushing through narrow gorges and widening unexpectedly into placid lakes, making nearly every part of the great area accessible to the canoe; the erratic morainal blocks and other materials, traceable to this area, found scattered over southern Ontario and the northern United States down to the Ohio River; the thin mantle of boulder clay and other glacial drift materials, left in irregular patches over much of the pre-Cambrian area; the faceted and striated boulders and gravel found in this material: moreover, the vast volume of elastic sedimentary rocks, leaning against the margin of the Shield, forming a large part of the remainder of the continent, and very evidently derived from materials once forming part of this highland; the absence of any clear traces of life in any of the oldest formations remaining in place — these and many other phenomena which are observed by the trained eye of the geologist, are so many symbols inscribed in Nature's scroll. Deciphered, as they have been, by the geologists of our Universities and of our Dominion and Provincial Governments, these symbols reveal a story of entrancing interest, particularly to Canadians. We can make only passing reference to their devoted and brilliant work, which must continue for a very long period of time, in unravelling the geological history, and assisting in the economic interpretation of the geological structures and formations, of this vast area, with the hope that some who have not yet done so may be tempted to look into this pre-historic volume concerning our country.

(To be continued)

### BISMUTH IN 1922

The quantity of bismuth sold in the United States in 1922, according to figures compiled by the United States Geological Survey, was 226,385 pounds, and the average price was \$2.26 a pound. The quantity sold including imported and domestic bismuth that was recovered in refining lead and ten bullion at three plants in the United States. About 300,000 pounds of bismuth was recovered at these plants in each of the last two years. The chief source of the bismuth recovered from tin refined in the United States is Bolivia; the chief sources of that recovered from lead are Mexico and the Western States.

London and New York are the principal centers of the market for bismuth. New York supplies the domestic consumers, most of whom are manufacturers of medicinal chemicals in the vicinity of New York, Philadelphia and St. Louis.

## LETTERS FROM READERS

## Mr Nichols Presents Views of Western Members

To the Editor,  
Canadian Mining Journal  
Sir; —

In the issue of the "Canadian Mining Journal" dated March 23rd, last, I note that you have repeated an interpretation of the proposed amendments to the By-Laws that is not the correct one. I therefore desire to state clearly wherein the error lies, as I feel sure that you would not wish that your paper should misrepresent the views of others.

In writing to you now, I am not expressing my views alone, but those of every one of the signatories to the proposed amendments, and of the many members, not confined to the West, who have endorsed the action that has been taken in their presentation. My statements may therefore be taken as authoritative in regard to what is really intended.

You say "It (the annual meeting of the Institute) was saved, curiously enough, by one of the very members whom our Western confrères would have us exclude... a non-professional member."

The Western members do not wish to exclude, but the object of the amendments is not to exclude, the non-professional man.

I am taking it upon myself to make this definite statement, which I know you will accept as being desirable for that better understanding that we all realize as essential and in which we are all interested, because I can see very well how this misconception grew.

Will you allow me to make one or two remarks in explanation?

You know that during the earlier part of last year there was much controversy about membership policy, and the air was so thick with conflicting issues that, interested as I was, (and I may say that I had been in correspondence with the Secretary upon the subject during the previous year), I waited until things had quieted down a little, and then sought to start though from another angle, from a point back of the field in which the campaign was being fought.

My feeling was, (and I submit this viewpoint now), that this matter of Institute membership is to be considered in three ways;

As a matter of principles, — The worth of an organization depends upon the worth of its members.

As a matter of Policy, — The character of the worth required is to be provided for in regulations.

As a matter of administration, — The regulations are to be carried out.

If you will do me the honor to look through my paper on the "Institute Idea", you will see that then I was discussing and trying to get others to consider, a principle, — I was not dealing with policy and I stressed this point when I introduced the paper at the western General Meeting in November. That point, apparently, was not quite understood and that is why it comes about that the amendments have been interpreted as they have been by you. The consideration of the principles involved was followed by the question of the policy to be adopted, and the recommendations were embodied in the amendments.

*ments, in collaboration with a great number of others, interested in them, was, and is, that the institute membership should not be restricted to professional men, but should be restricted to men of responsibility, or worth, in, and to, the industry. The dominant law, embodying stands, to be balloted on, members shall have been for at least five years in responsible positions with regard to practical mining and Metallurgical Work.*

Not technical positions, not professional positions, not scientific position, — just positions of responsibility.

I want to be perfectly candid. It is my own desire to see an Institute in Canada in which the bond among professional men may obtain a real and operative value. That is the reason why, in my paper on the "Institute Idea", I sought to show wherein that value lay, and to establish the principle.

Then came the question, — In what way, and to what extent can that principle be embodied in the policy of this Institute? This was a question of policy, and those who have indented themselves with the amendments, and those in favor of them, are openly stating that the essential is best served by providing that membership shall be restricted to men of worth, and not only professional men, — all men of worth, genuinely interested in the mining industry, to the extent of subscribing their worth to the building up of a representative body of influence.

As these are the facts, is it more than our due that we should ask you to place this construction clearly before the public in your paper, as an amendment to the previous statements based on misunderstanding.

There is another question, in addition to those of inherent principle and avowed policy, and that is, administration. It is not becoming, perhaps, at this time to discuss this matter; but I may say that the Council has under consideration certain means whereby better representation of opinion may be secured and the better exercise of its functions provided for. Is it not this that is wanted to ensure a democratic organization? Is it supposed that men with no interest, except to say that they are members by virtue of a \$10.00 annual subscription, are going to put thought and work and experience into the Institute such as that now being put in? I say this in no spirit of egotism, and I speak for others.

Vancouver, B. C.

H. G. Nichols

## Temiskaming Testing Laboratory's Rates for Assaying

To the Editor,  
Canadian Mining Journal.  
Sir; —

There is nothing more repellant to me than a public controversy, so it is with the utmost reluctance I write this letter.

In your issue of March 30th, you state, — "It is eminently desirable that the officials of the Department of Mines should have early and accurate knowledge of the development in the gold fields, that they may perform their public services the better. With this end in view the Laboratories at Cobalt have offered very attractive rates to prospectors and others. This would be 'all to the good' were it not for the existence of independent custom assayers, one of the most valu-

able adjuncts to a gold mining camp. It is said that the public laboratory has cut prices to a point that the private laboratory cannot meet..."

In reply Mr. A. A. Cole says in your issue of April 13th, — "In your last paragraph, your adverse criticism of the assaying department is based on false information and calls for correction".

It is my belief, Mr. Editor, that an experience I related to you at the Mining Institute meeting at Montreal prompted this criticism, and I want to state that what I said was not false, but correct to the last detail. So that Mr. Cole may understand your source of information, I will repeat my statement, giving facts and figures.

I opened a mining engineering and custom assaying office here, with an initial outlay of something over \$3000. To a poor man, and one who spent the three most productive years of his life in the C. E. F., this was a venture of some magnitude. The first week I was operating I received a communication from an engineer, asking me what my rate would be on a season's assaying of approximately 300 samples, weighing on an average ten pounds each, and stating that he was sending a similar letter to two other reliable assayers. I quoted him a rate of \$1.00 each, and I believe this to be the lowest rate at which an efficient assayer can do justice to himself. He came back personally and told me my rate seemed to correspond with one of the other offices, but was away high compared with the Temiskaming Testing Laboratories, as they quoted a flat rate of 75 cents each. Two other engineers tell me that they have been offered the same figure, — two of my steady clients, I might add.

I tell these people that it is simply out of the question for me to try to meet this price, and that I believe that no man with his own capital involved can work so cheaply, give good service and continue in business. Also, if I offered that rate to one, it would be my universal rate, because I could have no especially favored clients. Perhaps a Government subsidized laboratory, who can advertise "Owned and operated by the Ontario Government Department of Mines", and whose salaried executive always knows that there is an abundance of ready funds to take care of any financial emergency that might arise, may be able to work this as cheaply as this; but I cannot, and don't intend to try.

The upshot of the whole thing has been, as far as I am concerned, that the first man I mentioned sent about 150 samples to Cobalt, then switched his business over to me, telling me that he believed the better service and quicker returns warranted the additional expenditure. I do not think I lost any business with the other two, except when the power was off at the time of the Haileybury fire.

If Mr. Cole has forgotten the experience I related to you, Mr. Editor, (which does not seem reasonable), I am quite willing to recall the engineer's name and the circumstances to his memory; also to furnish the names of the other two engineers who have told me that they were offered the same rate. These men must, however, be protected from any undue publicity.

Now I have no further interest in this issue. One year's operation has taught me that I can stand the competition of the public laboratory. What has

prompted me to write this letter was the bald statement that your information was false.

Kirkland Lake, Ont.

Frank. H. Huff.

## POSITIONS OPEN IN OTTAWA

Applications for the following three positions will be received by the Civil Service Commission, Ottawa, until the dates mentioned.

5241—Two engineers, Mines Branch, Department of Mines, to commence at a salary of \$2,100 a year with yearly addition of \$120, plus bonus as may be provided by law. One engineer will assist in the Division of Mineral Resources, and the successful applicant's first work will be to examine alkali deposits in the West. Applications for the position will be received up to May 10th.

The second engineer, with similar salary, will assist in the operations of the Division of Ceramics and Road Materials, both in the field and in the laboratory. He must be already experienced in ceramics. Applications will be received up to May 21st.

5242—An assistant in the Mines Branch is to be appointed at an initial salary of \$1,680 with annual increase of \$120 and bonus as provided by law. Field and laboratory work will be included in his duties. Applications will be received up to May 10th.

Candidates are required to be university graduates, or the equivalent, with subsequent practical experience. Application forms can be obtained from Ottawa, from any office of the Employment Service of Canada, or from postmasters in the principal cities

## PROBABLE LIFE OF JOHANNESBURG

Johannesburg, South Africa, is merely a mining town whose seeming permanency is due to the persistence of the gold reefs of the 'Rand and their gold content. This is the gist of some discussion reported recently in the "S. A. Mining and Engineering Journal". The present resources of the working mines are estimated at 300 million tons containing over 6 dwts. per ton in value. In addition there is estimated to be 724 million tons of ore of lower grade, which may become workable if extraction processes are improved or mining methods cheapened. As the ore, is being mined at the rate of 26 million tons a year, an 11½ years' supply of milling grade is assured. It is probable that ore of the second category will be used largely to supplement this supply. As the prosperity of the whole of South Africa, as well as Johannesburg, depends very largely upon the 'Rand's gold production, this question of its duration is very highly important to the Union.

The copper industry in the Katanga province of the Belgian Congo is, next to the 'Rand gold mining, the most important mining operation on the African continent.

The present lack of adequate prospecting in South Africa is causing comment among those interested in the mineral industry. The "lone prospector" has almost ceased to exist, and the great expense of developing a find has proved a deterrent even to syndicated prospecting.

## Opportunities for Prospectors in Portland Canal District

When it is borne in mind that the Premier Mine in 1922 produced nearly as much gold and almost double the amount of silver as was won in the entire province of British Columbia, including the Premier itself, in 1921, it is not surprising that the Portland Canal District, in which this property is situated, is at present one of the outstanding attractions of the entire mining and industrial world.

Since the Premier came into prominence not much more than two years ago there has been mining development, more prospecting, and more road and trail construction in the Salmon River section of this mountainous region in the northwesterly corner of British Columbia than has been crowded into so short a space of time anywhere else in the West for many years.

A parallel might be found in the Cariboo gold rush of the '60's, or in the later mining booms of the Slokan or of Rossland; but in recent years there has been nothing like it on the Pacific side of the prairies. The movement has not yet obtained its full momentum. As has been stated, the success of the Premier Mine is the finest advertisement British Columbia mining has had for years. Its value recently was accentuated by the exceptionally concise and conservative, but none the less wonderfully impressive report of Mr. H. A. Guess, president of the Premier Gold Mining Company. That there is to be more activity this year in the mineral zone of which the town of Stewart is the gateway than ever before, has been forecasted by George Clothier, resident mining engineer, and his prediction has been substantiated by recent events as well as by the accounts of every mining man who has come out of the country during recent months.

### Travel Routes Centre at Stewart

The announcement was made by the Hon. T. D. Pattullo, Minister of Lands, only a short time ago that the government proposed putting several hundred of its lots in the town of Stewart on the market. As a matter of fact this sale has been definitely set for May 14th, which is to say that the provincial authorities are convinced that the time has arrived in the growth of that mining community to give all interested an opportunity of obtaining building sites.

Stewart is the Canadian entrance to the new western Eldorado. From that point one can travel in any direction inland. Motor cars can reach Bitter Creek, a distance of eight miles. For fourteen miles up the Bear River there is a good wagon road, with branch horse trails up the main tributary creeks. The main road is continued as a first-class horse trail up the river over the divide to Meziadin lake, forty miles from tidewater. There is a first-class motor road from Stewart to the Premier Mine. Of this, the first two miles are in British Columbia, connecting with the Salmon River road; at Hyder, Alaska; and continuing for thirteen miles in American territory. The last three miles are on the Canadian side. The provincial government is constructing a branch from this road to the upper valley of the salmon river and serviceable horse trails have been built from the Premier road, one of which

goes over the divide on to the Long Lake side and the other over the divide to the Naas slope following the Missouri ridge. Any point down the Portland Canal can be reached by launch; to Maple Bay is a little over 30 miles; to Georgia river about 15 miles, with a government trail up the river for about 5 miles; to Marmot river is about 4 miles, with a good trail to the heads of both forks. It is clear, therefore, that this mining division has been made very accessible in all parts of the more prospected areas.

### Unuk Basin a Promising Area

It is probable that some prospecting will be done in the Unuk River basin this season. Mr. Clothier has said more than once that, in his opinion, there is good mineral bearing country "east of the granite, about twenty miles from tidewater." At present it is somewhat difficult to get into, but no doubt some hardy and experienced prospectors will be successful. There is a possibility that it will be opened up by trail before long. Mr. Clothier is known to be in favor of this. Upon his recommendation the Provincial Mines Department, in co-operation with the Works Department, has done most of the road and trail construction that has been sketched. He still, however, is far from satisfied. Last year he experimented with the building of cheap "exploration" trails into unprospected mineral areas. Twenty-five miles of such trail was slashed out, down timber cut out, and footbridges thrown across creeks, starting from the Bear-Naas trail north to Surprise Creek and along the east slope of the range. It is probable this policy will be applied in the opening up of the Unuk River basin.

Encouragement to those planning to prospect in the district is found in the fact that it is authoritatively asserted that hitherto prospecting has been confined very largely to showings already discovered and to a more thorough searching of claims already staked. Government statistics show a distinct increase in the number of claims staked last year and the assessments recorded, but this is not accounted for by the opening up of new sections so much as the gradual extension in the known mineral areas. Over 700 claims were recorded in the Portland Canal District last year, 1,200 assessments were done and about 1,000 prospector's certificates issued. These figures will be substantially increased in 1923 if the prophecies of those closest in touch with the situation are borne out and if the reports as to the number of prospectors arranging to go north as soon as the season opens up are well founded.

### Geology of the District

Mr. Clothier divides the district in question into three parts geologically, viz. the Coast Range Belt, in the centre, the Eastern Contact Belt on the eastern flank of the Coast range and the Western Contact Belt of the western flank. The importance of the Eastern Contact Belt has been emphasized by the Premier Mine's output and profits and it is observed that "it is worthy of consideration that where there has been any extensive prospecting and development work along this belt the results have been encouraging. At Kitsumgallum Lake; at the head of Kitsault and Illiance

ivers; at the head of Portland Canal, on the Bear, Salmon and Marmot rivers; and in the Atlin section, in the Engineer mine vicinity, are the only 'spots' where this mineral belt has been explored to any extent. In these isolated places, aggregating probably sixty miles along the belt, there have been developed the Dolly Varden, Premier, and Engineer Mines. There remains a distance of over 300 miles in this district alone, along identically the same belt, in which, as yet, there has never been heard the sound of the Prospector's pick."

### Properties Under Development

As to present conditions, the whole world knows of the Premier Mine, its high-grade ores and large bodies of lower-grade milling ores, its modern plant at the mine, its eleven-mile aerial tramway with first-class bunkering facilities at tidewater, and its production and profits, so that it is unnecessary to do any more recapitulation than thus to recite the facts. But it was not the only property under development last year, nor will it be the only one receiving attention this summer. In the Portland Canal country in 1922 considerable work was done on the Outsider Group at Maple Bay; the Sunshine Group on Glacier Creek; the Mobile and Prince John Groups on the Bear River; the Indian and B. C. Silver Mines; as well as several properties on the Alaskan side of the Salmon River. If the Atlin district is included — and it should be because its minerals are on the same contact and the section is immediately adjacent — work of a serious and promising character was done on the Atlin silver-lead mines, the Engineer Mine received some attention and shipping ore was opened up and some shipments made from the Maid of Erin Group in Rainy Hollow. Several of these properties have exposed large tonnages of ore and may be expected to begin shipping regularly in the near future.

Many prospects were worked last summer but closed down in the winter and among those of this class in the Portland Canal zone were the Patricia and Idaho Groups on the Marmot River; the Silverado Group at Stewart; the Mimico and Evening Sun Groups, Glacier Creek; the George Group, Bear River; the Outland, Betty, Big Missouri, Unicorn and others in the Salmon River Valley. And there were still others on the Alaska side of which good reports are heard. This indicates that exploration work has been the feature of recent activity and it may be expected that the same will continue true this year, although, as has been stated there is no doubt that much more prospecting will take place.

### Three Near-Mines

Naturally there is much speculation as to the possibility of another Premier Mine being developed and on this point it is well to bear in mind that it took fifteen years to bring this property to the position it now occupies. Still, there are a few holdings that have been more intensively explored than others of late and the development of which, because of their promise, will be closely watched this year. One of these is the B. C. Silver Mines, Ltd., a group adjacent to the Premier. This company's success in outting the extension of one of the important ore producing fissures of the Premier and the satisfactory values obtained across a width of 25 feet, has caused much excitement. There is every reason to believe that it will become an important

producer. Large bodies of milling grade ore have been developed on the property of the Indian Mines, Ltd., which is another property worth keeping an eye on. The Big Missouri, turned down after examination by mining authorities, but whose worth has been stoutly upheld by other authorities as well as by practical miners intimately acquainted with local conditions, gives indications of "coming back" and of proving that the most talented of geologists sometimes err. The results of last year's work were encouraging and it is said that further geological data may entirely alter the complexion of things. The work will be continued this year. The development of the Prince John Group on Bear River, of the Dunwell Mines, Glacier Creek, and of the Mobile Group, Bear River, are all operations that are being followed with much interest.

### Granby's Activities

Any attempt to summarize the mining situation in and around Portland Canal would be lacking in one of its essentials if no reference were made to the Granby Consolidated Mining & Smelting Co., which has its smelting centre at Anyox and whose ramifications extends not only throughout the northwestern part of British Columbia, but have again spread to the southern field. This Company is to Alice Arm, the Salmon and Bear River regions, and the adjacent areas, what the Canadian Consolidated Mining & Smelting Co. is to the Kootenays. The positions of the two are analogous in most respects although perhaps the independent operators of the northwest are somewhat more independent, if they care to be or if it is necessary, because the Tacoma Smelter a few hundred miles further to the south can be easily reached by water.

The enterprise of the Granby Company, however, has had, and unquestionably will continue to have, an important bearing on the development of the mineral resources of the district under discussion. Last year they employed in all departments some 1,100 men. From the Hidden Great mines there were mined 854,714 tons of ore, producing 30,334,180 pounds of copper, 386,264 ounces of silver and 8,901 ounces of gold. The coke and by-product plant was in continuous operation and turned out 52,305 tons of coke. The power plant at Anyox is being added to by the construction of a dam, which will be completed this year, and a 1,000-ton concentrator of three units is to be built. That a policy of expansion in the North has been decided upon, and that the Company proposes to increase its reserves well beyond those available at the Hidden Creek Mines, is apparent from the fact that they recently bonded three copper properties in the Portland Canal section, viz., the Outsider, Maple Bay; the Sunshine Group, Glacier Creek; and the George Group, near the head of Bear river. The successful development of the George Group, Mr. Clothier states, would be of special importance to the Stewart district, as it would mean the operation of the Portland Canal Short Line Ry. and its extension to the Bear River pass, where the property is situated, thus giving a further distance of six miles along the Bear River railway facilities and bringing the area beyond the Bear River divide within range of transportation.

In the Mineral Survey District No. 1 last year there were mined 1,065,758 tons of ore, which produced gold, 167,736 ounces, silver 4,684,944 ounces, copper, 31,054,010 pounds; and lead, 14,285 pounds. These are increases in comparison with 1921 in all cases with

the exception of in copper. The gold output is practically double that of last year and is three times that of 1920. The silver represents the greatest production of that precious metal ever made in one year in any one district of the Province. This is due, of course, to the Premier Mine.

Will the Portland Canal District develop other equally phenomenal producers? There are many pros-

pects just as promising as the "wonder mine" was in its earlier stages; some of them are distinctly more encouraging; engineers and practical mining men are a unit in asserting that there is no reason why the Premier's record should not be repeated in this district. Certain it is that earnest prospecting, exploration and development is to proceed this year on a scale never before equalled in this section of British Columbia.

R.D.

## Quebec's Gold Fields to Have a "Grand Opening"

By ALEXANDER GRAY

Dr. H. C. Cooke's article on the economic geology of the Opasatica-Duparquet areas of Quebec, presented in the "Canadian Mining Journal" recently, provides chapter and verse for "Bush Baptists", those intrepid apostles who blaze their way. The blueprints obtainable from Quebec Mines Department (now being run off in editions) attest the aggressiveness of the movement and the active interest of corporations, individuals and syndicates of more or less influence and ability to finance field operations. Two essential preliminaries, therefore, have been provided and Quebec's prospecting season starts under excellent auspices, more impressive, perhaps, than those attending the initial efforts in any other district since Poreupine.

### Gold District is Difficult of Access

Strenuous effort intelligently directed and adequately fortified with cash are pre-requisites to a thorough preliminary examination of the townships staked, and to be staked, for the movement has lost no momentum. Poreupine was none too accessible. Kirkland Lake was alongside a railway. Larder Lake, and now Quebec, will have relief in the near future, via the Temiskaming and Northern Ontario or the Canadian Pacific, as well as the Transcontinental Railway. After all there is a compensating factor in having mining country where its potentials require vigorous treatment "so near and yet so far." Smuts put the matter neatly on one occasion when Boer farmers were complaining of conditions and upbraiding the Transvaal Government for not doing more. The fighting scholar listened patiently to the complainants and then remarked: "Do you know what is the real trouble with you farmers?" A series of replies covered every ill, real or imaginary.

Smuts then had his say: "Your chief trouble is that the ground is too near".

### Substantial Interests Involved

Backbone, the weight of physical forces, bending to the task, was Smuts' remedy. And so it is with Quebec's gold fields. They have attracted certain of the established Cobalt companies; dominant owners in those companies; innumerable capitalists who joined in similar prior movements; and it is understood by all these that the making of gold fields differs radically from the immediate returns obtained from Cobalt's bullion ores. During the Montreal River era it was learned that Cobalt is alone of its kind. The

catalogue of Montreal River companies would make a substantial directory of those identified with North Country mining. Poreupine likewise attracted many, but held a few. History then repeated itself—closer to transportation than the Quebec fields. However, experience was gained, and Quebec is to get the cumulative benefits. Larger field parties, fully equipped, the knowledge gained from contacts and shearings, and the futility of acreage without fractures, will give Quebec a speedier certificate of character. The ground is not so near, its contents will have to be stooped for, and there is the assurance of Dr. Cooke that the Pontiac and Temiskaming Series are identical, the only difference being that the Quebec section "has been much more strongly folded and metamorphosed" and is "more widespread and thicker".

Distance lends enchantment—until there is disenchantment. Enough has been ascertained about the Quebec fields to give them a probationary status. "Sweat" was the Smuts antidote for taciturnity and impecuniosity. The sturdiest of types is the "Bush Baptist", who bathes (when he has to) in the snow and swathes himself in perennial optimism. Given the requisite effort of those now represented on the field, it is to be expected the results will speak for themselves, without prospectuses.

### The Claims Under Development

The Cockeram-Powell-Horne lines in Rouyn township are occupied by responsible organizations. Exactly who has both the Cockeram and Powell veins, as they are designated, cannot be stated with definiteness. The Hammell-Cockeram (cornering on the St. Louis property) is held by a strong syndicate engaged in diamond drilling. What are the values thus far secured from the two cores, to a depth of 100 feet, is a subject for conjecture. Outcropping values were variable, but are said to have averaged satisfactorily.

A series of boreholes will be necessary to determine those values at depth, and along a lateral distance sufficient to make tonnage, as well as to justify the purchase price. Two lines of break provide incentive for the Cockeram holders to pursue their exploration work.

On the south, the Thomson-Chadbourne party (mostly, if not wholly, New York people) have a camp and a prospecting plant in position. Ascertained

values at outcrop convinced Mr. Thomson, a mining engineer of wide experience, that this Powell property had the necessary elements to make a mine. So he associated with himself and Mr. Chadbourne several former technical colleagues and some London principals. Undoubtedly the Powell and Cockeram claims are held by men competent to develop the mines, if there are no underground disappointments.

To the northeast of the Cockeram, the St. Louis ground is held by the syndicate managed by O'Brien and Williams, Montreal stockbrokers, and in which Fred. Connell, Hugh Doheny and others are interested. A camp has been provided and the intention is to locate, if possible, the extension of either the Powell or the Cockeram vein.

Indications are favorable at other points around Lake Osisko. Further south, around Pelletier lake, it is hoped to find correlative conditions. From south of Rouyn lake to and beyond the big bend in the Kinojevis river, there are reports of discoveries on the Davidson, Cavers and other properties. As this section soon will be accessible by water routes from the north and the south, exploration parties will be able to prosecute their work under better conditions, Rouyn township from east to west is occupied.

#### Boischatel Now Staked Throughout

Boischatel township had secondary consideration until the import of Dr. Cooke's study of the situation became known. Now the township is fully staked and more attention is being given to the pioneer properties in the vicinity of Fortune lake, the Lake Fortune Mine and the King of the North, both having geological features more clearly comprehended now than formerly. In or close to the shear zone mentioned by Dr. Cooke, the Lake Fortune and King of the North properties may undergo a revision of judgment, when they are financed and exploration is resumed. Along the shear zone described by Dr. Cooke the country is highly mineralized. Porphyry masses have been noted and quartz outcrops are promising. Not much has been heard from the Township of Dasserat, to the west of Boischatel. It is known that the porphyries extend across the height-of-land into Duprat township.

When the snow blanket is off, Quebec will have mass movement. Cobalt companies did not take Porcupine seriously enough. Individual Cobalt men bestirred themselves and acquired Pearl Lake areas. Apart from the Beaver-Temiskaming, no Cobalt company benefitted from Kirkland Lake. Crown Reserve has great expectations about its Pancake Lake property. The "negatives" of Cobalt, were in the majority in the gold country; but it may be South Lorrain will provide compensation and that Quebec will meet with favor. At any rate, Coniagas has holdings in Rouyn township. It is not apparent that the Mining Corporation will do likewise, as yet. Senator M. J. O'Brien's representatives are understood to have located in central Boischatel. The stage is set and more than scenery should come into view when the snow curtain is raised. But, of course, many of the participants will not have a speaking part.

The output of asbestos in Southern Rhodesia during 1922 was 14,248 tons, while for January, 1923, it was 1,708 tons.

#### ECHOES FROM CONFERENCE ON RESEARCH

The Canadian Manufacturers' Association has just published the proceedings of the conference on research it convened in Ottawa in February last. In it will be found much food for thought by those interested in the industrial progress of the Dominion. One of the outstanding addresses, that of Dr. C. V. Corless, has appeared already in these pages. Following are short extracts from some of the other addresses.

In outlining the Advisory Research Council's work, Dr. Frank D. Adams said:

##### Conditions in Britain

"The British Research Council with the great fund its disposal (£2,000,000) has approached the various industries of Great Britain and has induced some twenty-three of them to organize themselves, and they have established a separate laboratory for the study and solution of their respective industrial problems and for the improvement and cheapening of their manufacturing processes. Each industry has subscribed a large sum of money and the Research Council has added to this an equal sum, and the special research laboratory for each industry has thus been started.

"In Canada conditions are quite different. The industries are fewer and not so wealthy and the Canadian Government is not in a position to subscribe \$10,000,000 in aid of research.

##### The Canadian Scheme

"Research Council of Canada are consequently recommending to the Government a plan for the development of industrial research which is much less costly and which meets Canadian conditions.

"It suggests that the government and the industries of Canada, of whatever kind they may be—manufacturing, mining, metallurgical or agriculture—co-operate and work together in the development of a single national research institute. This may be erected in Ottawa or in one of the great industrial centres of the Dominion as the government may decide. The proposal is that the government as its share will erect and equip a suitable building for the research institute and will provide a certain sum annually for its upkeep and for the salary of a director and two assistant directors—all men of marked ability and experience in research. The industries will then when they have any problem to solve, come to the institute and submitting it to the director, will be provided with a laboratory space and full facilities for carrying out the required work. The director will secure for them a properly qualified man to carry out the investigation under his direction, whose salary and the expenses entailed (apart from overhead charges) will be borne by the industry or firm for whom the work is being done.

##### The Mellon Institute

"Many most remarkable and brilliant discoveries saving hundreds of thousands of dollars, and effecting immense improvement in the whole range of industries in the United States have been made by investigations of this kind and carried out on exactly this plan at the Mellon Institute at Pittsburgh. Even such a primitive industry as bread making, while having been known and practised ever since mankind emerged from their

most primitive and savage state—and about which we might be supposed to know everything that could be known—has been subject to several distinct improvements through investigations carried out and discoveries made at the Institute for the Bakers' Association of the United States. The history of the work of the Mellon Institute is so striking that it reads like a veritable romance.

These advantages should be placed at the disposal of the manufacturers of Canada if they are to be placed in a position to meet their competitors in other countries as the rivalry in trade becomes more intense, and it is believed that all these would be provided for them by the establishment of a national research institute.

### Will Canada Remain Last in the Race?

Col. F. M. Gaudet, formerly Technical Executive Officer of the Advisory Research Council, and himself well experienced in practical benefits of industrial research, concludes his remarks thus: "What are we doing in Canada today? What are we doing to help our industries and manufacturers? We are doing nothing. . . . Some of our rich corporations are doing little, but what we want is the establishment of a research institute that will be a guide in all these matters. We want to focus our efforts and our energies in such a way that we shall get the best results."

Mr. Hume Cronyn, formerly chairman of the parliamentary committee on research, outlined the past and present effort in respect of research by the leading industrial nations of the world. Britain has made wonderful strides since she awoke to the peril of her position in 1915. The United States is far in the lead. Canada is woefully behind. Mr. Cronyn concludes by saying: "Are these other nations, who are making large expenditures on scientific research, chasing a will-o'-the-wisp? Can this idea be a mere fad or dream? As Dr. Ruttan has pointed out, we are the only British Dominion that has not actively taken steps towards the establishment of a national research institute. Are all the others out of step? Is Canada alone marching forward?"

### ARSENIC OUTLOOK IMPROVING

The output of new refined and crude arsenic in the United States in 1922, all of which was sold, amounted to 9,350 short tons, according to final reports received from producers by the United States Geological Survey. Additional sales from stocks brought the total quantity marketed to 10,027 tons, valued at \$1,475,229. The sales of crude arsenic, 70 to 94.8 per cent pure, amounted to 1,122 tons, and the average selling price was 6.2 cents a pound at the plants. Most of this material was converted at the places of production into sodium arsenite for killing weeds, and small lots of it were exported for agricultural use. The sales of white or refined arsenic, 99.5 per cent pure, amounted to 8,905 short tons, and the average selling price was 7.5 cents a pound f.o.b. refinery.

The imports of white arsenic, according to the Bureau of Foreign and Domestic Commerce, amounted to 210 tons up to September 21, 1922, when the new tariff law became effective. During the rest of the year, ac-

cording to reports from brokers, 307 tons were imported, which brings the total supply of white arsenic for the year up to about 10,600 tons.

The minimum possible demand for white arsenic in 1923 was placed last December at 12,000 tons, but the demand now expected will be much greater. For example, the minimum demand included only 3,500 tons to be made into calcium arsenate, where as the demand may be 7,200 tons. As already shown by B. R. Coad, of the Bureau of Entomology, Department of Agriculture, as much as 25,000,000 pounds of calcium arsenate, equivalent to about 5,600 tons of white arsenic, may be available for use as insecticide during the season of 1923, so that there will probably be some shortage of calcium arsenate, though it will not be so great as was at first expected.

The estimated production in 1923, based on operations in the first quarter, is placed at 22,000 tons of refined white arsenic and 5,000 tons of crude white arsenic. The imports from Mexico may amount to 5,000 tons, and those from other countries will probably raise the total to 35,000 tons. This estimate does not include the possible output of several small operators who may further increase the domestic output before the end of the year. It appears, therefore, that as soon as the spring demand from manufacturers of insecticides declines the supply of white arsenic will be sufficient to supply all needs.

Owing to the high prices quoted for white arsenic in 1922, buyers in New York reported that they had received offers in December from several foreign sources. One thousand tons annually was promised from Greece and current supplies were offered from Australia, Belgium, Germany, and France. The belief has been expressed that with increased production at home and abroad the potential supplies for 1924 are increasing rapidly, and that after consumption begins to decline, next August, there may be a rather serious though temporary break in the market after which the price of white arsenic may become established at 8 to 10 cents a pound.

A stable price of 8 cents or more a pound and continued growth of demand may encourage the enlargement of active by-product white arsenic plants and the establishment of new plants at certain of the greater smelters. Direct production cannot furnish cheap arsenic but the establishment at favorable points of plants for the recovery of arsenic and the reshipment of the residues to smelters for recovery of precious and base metals may be advantageous to the miner, the smelter, and the consumer. Arsenic sulphide ore and concentrates require but little fuel, and their roasted residues can be smelted more cheaply than the original ores or concentrates. The success of such an arsenic plant necessarily depends upon a continued steady or increasing demand for domestic arsenic.

According to the Chinese Ministry of Agriculture and Commerce, the total coal production in China for 1922 amounted to about 21,300,000 tons, of which 5,500,000 tons were produced by Chinese mine-owners. This figure has doubled that of 1916, when the Chinese coal owners claimed a production of only 2,800,000 tons out of a total output of 16,000,000 tons estimated for the whole of China.

## PHOSPHATE ON NAURU AND OCEAN ISLAND

While Florida holds the record as a producer of phosphate rock, with 3,255,720 tons in 1920, and with scores of million tons of reserves determined, and while Morocco is now known to possess vast beds of phosphate, far inland, there is a British possession on the opposite side of the globe whose importance ranks with either. Nauru and Ocean Island, tiny specks in the Pacific a few miles south of the equator, 2,200 miles northeast of Sydney, Australia, and directly north of New Ireland, are now being actively worked for phosphate, recent shipments having exceeded 300,000 tons a year. They are 165 miles apart, and each is the tip of a high submarine mountain, the Pacific being very deep in the immediate vicinity. A comprehensive description of the islands is given in recent numbers of "Industrial Australian and Mining Standard." Nauru has an area of 12 square miles and it has been estimated that six-sevenths of this is phosphate-bearing. The rock is mined by hand in open-cuts and drawn on a light railway to a rotary drier, whence it is trammed to storage heaps or to a pier for loading. The island is encircled by a coral reef, on which is built a steel cantilever that discharges the phosphate into small lighters. These lighters are discharged by winches on the cargo steamer anchored a few hundred yards farther out. A longer cantilever, by means of which ships can be loaded direct from the shore, is to be installed. Most of the phosphate is shipped to Australia, and a smaller part to New Zealand and Britain.

Ocean Island is about one-third the size of Nauru, but its phosphate rock is phenomenally rich. It is worked in a similar way.

The temperature on these islands is equable, varying from 85 to 90 deg. F. throughout the year. Heavy rains prevail from November to February. On the island of Nauru there is a fresh-water lagoon, and the fertile soil supports an indigenous population of about 1,200—fine, sturdy people of a negroid type who have a tribal system of government. On Ocean Island there is no lagoon, the native population of 500 having had to subsist on rain water, collected in pools and in caves, until the advent of the phosphate miners. To supplement the supply of native labour, New Guinea "boys" have been brought in recently.

The phosphate deposits of these two islands were mined formerly by a private company. They are now operated by a commission appointed by the British, Australian and New Zealand governments, who bought out the rights of the private owners in 1919. Australia is getting at present the major part of the phosphate rock, and the government intends to reel it at the lowest possible rate. The price has been, until recently, 75s to 80s a ton. At present the price varies from 55s. 6d. per ton in the eastern states of Australia to 58s. 6d. in the more distant western states. It is expected that these prices will be materially reduced in the near future. It may be noted, in comparison, that Florida phosphate is now worth between \$6.00 and \$7.00 at the quarries.

The output of cement in the United States during 1922 was 114,789,984 barrels, valued at \$1.76 a barrel, which is 16 per cent above the output of 1921, and is the largest on record.

## ALUMINUM CHEMICALS IN 1922

In 1922, 281,480 short tons of aluminum salts valued at \$8,813,000, was produced from bauxite and aluminous clays according to figures compiled by the United States Geological Survey. These figures compare with a production of 184,820 short tons in 1921, having a value of \$7,546,000. In 1922 there was consumed in the manufacture of aluminum salts 162,980 tons of bauxite, valued at \$2,305,000, and 11,428 tons of high-alumina clay, valued at \$114,280, as compared with 64,380 tons of bauxite and 9,830 tons of high-alumina clay in 1921. The value of the new aluminum (metal) produced in 1922, was \$13,622,000, and increase of about 25 per cent over the value in 1921.

In 1922 six companies produced 8,305 short tons of ammonium alum, valued at \$535,760, and three companies produced 9,506 short tons of sodium alum valued at \$570,370. Some potash alum was also produced.

Alumina in both hydrated and calcined form was produced by two companies and was used largely in the manufacture of other aluminum salts, particularly iron-free aluminum sulphate.

Five companies reported a production in 1922 of 4,039 short tons of aluminum chloride, valued at \$289,500, as compared with a production in 1921 of 5,650 short tons, valued at \$552,300.

Commercial aluminum sulphate was made at 19 industrial plants and 9 municipal waterworks in 1922, as compared with 19 industrial plants and 5 municipal waterworks in 1921. The aluminum sulphate sold in 1922 amounted to 231,390 short tons, valued at \$6,090,170, as compared with 154,920 tons in 1921, valued at \$5,525,100. Municipal water-purification plants reported the manufacture and use of 6,075 short tons of "Hoover" alum, valued at \$126,095, in 1922, as compared with 3,060 short tons, valued at \$53,839, in 1921.

Iron-free aluminum sulphate was made at 7 plants in 1922, the total production being 19,160 short tons, valued at \$968,650, as compared with 11,000 short tons, valued at \$592,100 in 1921.

The imports of alum cake from January 1 to September 21, 1922, inclusive, were 2,033 short tons, valued at \$80,763. During the same period 135 short tons of alumina, valued at \$8,749, was imported. The exports of alumina (bauxite and other aluminum ores) in 1922 amounted to 19,617 long tons, valued at \$961,208.

The average prices of aluminum salts in 1921 and 1922, as reported to the Geological Survey by manufacturers, are given in the table below.

| Salts                | Average price per short ton. |      |
|----------------------|------------------------------|------|
|                      | 1921                         | 1922 |
| Alum:                |                              |      |
| Ammonia . . . . .    | \$69                         | \$64 |
| Potash . . . . .     | 1.103                        | 70   |
| Sodium . . . . .     | 49                           | 70   |
| Alumina:             |                              |      |
| Calcined . . . . .   | 114                          | 115  |
| Hydrated . . . . .   | 119                          | 76   |
| Chloride . . . . .   | 98                           | 71   |
| Aluminum Sulphate:   |                              |      |
| Commercial . . . . . | 36                           | 26   |
| Iron-free . . . . .  | 54                           | 50   |

A number of mines at Broken Hill, Australia, are preparing to resume operations.

# The Mining Districts

BY THE JOURNAL'S CORRESPONDENTS

## NORTHERN ONTARIO

**Power for Hollinger.** — It has at last been officially announced that the Hollinger has obtained the rights from the Ontario Government to the Long Sault power on the Abitibi River, with permission to develop 25,000 h.p. The Province retains rights on any surplus power the mining company develops. It has been reported a number of times that negotiations for the power had been concluded, but these announcements were premature. The mining company will, of course, be influenced in its programme of development by the result of the action now being tried in the Ontario courts. This action is the case of the Northern Canada Power Company against the Hollinger to determine if the Hollinger agreed to sign contracts for all its power requirements. If the Northern Canada Power Company is successful in its contention it is difficult to see what the mining company could do with the power development.

**Break-up Ends Acute Power Shortage.** — Warm weather during the past few days has entirely changed the power situation in the Porcupine district, and the mines will now be able to obtain all the power they require. The spring has been very late and this has necessitated cut after cut in the supply of power until a few days ago the mines were receiving only a very small fraction of their normal requirements. Plenty of power will also no doubt, have an effect on the labor situation, because a large number of men have had to be laid off and this breeds dissatisfaction, which culminated in a demand for higher wages. With plenty of work for everybody there is less likelihood of trouble, and it is understood that the radical element throughout the camp is not meeting with the support it had anticipated. It is quite probable that wages may be raised, but not to the extent the Union has demanded.

**South Lorrain.** — During the month of March the Lorrain Operating Company, which is the Mining Corporation's subsidiary for the development of the Frontier property in South Lorrain, produced 184,817 ounces. This production puts the Lorrain property among the largest silver producers in Canada. The company reports that stoping operations were continued on the Woods vein, and that satisfactory progress was being made in development and exploration work. Encouraged by the success of the Mining Corporation and the Keeley, several new companies have been formed, some of which have placed their shares on the market. Among these is the Caribou Lorrain Silver Mines, with a capital of \$2,000,000. Arrangements have been made for financing the company, and it is proposed to start active development early in the summer. Brokers are giving a good deal of publicity to Lorrain Consolidated, which has properties adjoining the Keeley and the Mining Corporation. Close proximity to producing mines, however, does not necessarily mean that these claims will be producers themselves.

**Cobalt.** — It is proposed to re-open the Cobalt A-53 property in Gillies Limit and to let a contract for

drifting on the 100-foot level. This property has a considerable area of conglomerate, in which small veins have been found. While development work to date has not shown anything of much value, the property is considered a rather promising prospect.

**Larder.** — A new vein has been found on the 375-foot level of the Associated Gold Fields at Larder Lake, which is about 20 feet away from the main vein and has a width of 7 feet. No assays have yet been reported, but the vein is understood to look quite promising.

**Kirkland.** — The Grenfell Kirkland Gold Mines Limited, with a capital of 2,000,000 shares of \$1.00 par, of which 1,500,000 shares remain in the treasury, has been formed to take over the Stitt claims in Grenfell township. Sufficient funds have been arranged for to start work on the property, and it is proposed to unwater the shaft and do some drifting at the 100-foot level. The property has been known for several years and has small veins in which some good ore has been found.

The Kirkland Gold, which is controlled by the Beaver, is meeting with the best success the company has had since it started, and it is understood that during the month of March profits were in the neighborhood of \$10,000. A new vein has been discovered which is being developed on the 700-and 800-foot levels. The ore lies mostly in the contact between the lamprophyre and the porphyry, but in places lies wholly within the lamprophyre and gives good values in that formation, which is a very unusual thing in the Kirkland Lake district.

Several small developments are under way throughout the Kirkland district, which will result in a good deal of activity during the coming season. The Osweka Gold Mines proposes to commence exploration work as soon as possible. The company owns 160 acres in the immediate vicinity of properties recently taken over by the Tonopah Mining Company of Nevada. The Blanche River Kirkland Gold Mines, Limited, with a capital of \$3,000,000 in one-dollar shares, has been formed to take over and explore claims lying between Swastika and Kenogami Lake. The Vindicator Mines, adjoining the Wright Hargreaves, plans to start work in May and will do surface trenching and diamond drilling. The Rose Gold and Silver Mines, Limited, has been formed to take over properties in the vicinity of the Crown Reserve claims, and funds are being raised for diamond-drilling and shaft-sinking. The Highlands Kirkland will let a contract to sink its shaft from 50 to 100 feet in depth, and to explore a vein that was cut by diamond-drill. It is understood that additional diamond-drilling will be undertaken as well. A Peterborough syndicate is financing work on the Bruce claims, northeast of the Crown Reserve property.

**Nickel Company Resumes Operations.** — It is announced that Norwegian interests have financed the British America Nickel Corporation to the extent of \$1,500,000 and that operations are to be resumed at their plants immediately. Approximately 700 men will

be employed at the mines and smelter in Sudbury and about 300 at the refinery near Ottawa. The plants of this corporation have been closed down for several years, but now the company is understood to have obtained long-term contracts with large American steel producers.

**Gold Ore at Cobalt from Schreiber.** — A twenty-ton shipment of ore from the Foster claims near Schreiber has arrived in Cobalt, and is being sampled by the Temiskaming Testing Laboratories. This ore is being shipped under the provision whereby the Government will purchase ores from prospectors in an effort to stimulate development by means of giving accurate information regarding values.

**Porcupine.** — A contract has been let for diamond-drilling the Porcupine-Keora, and several holes will be put down on the south end of the property.

### ALBERTA

**Coal Output Increasing** — The production of coal in the Province of Alberta is showing an increase. Last January 245,300 tons more were mined than in the same month last year. The total output for January 1923 was 845,806 tons which amount is made up of 347,673 tons of what is classified as domestic, 74,457 sub-bituminous and 423,676 of bituminous. In January 1922 there were produced 312,871 tons of domestic, 30,989 sub-bituminous, 246,788 bituminous and 9,758 anthracite. In January 1922 some 829 tons of domestic were shipped to Ontario while in January of this year the export to that eastern Province totalled 5,239 tons. Shipments to adjacent provinces also are growing so that it is clear that the campaign being carried on by the Alberta Collieries, assisted by the authorities of the Provincial and Federal Governments, already is bringing results.

### BRITISH COLUMBIA

**Natural Gas on Thompson River** — At several points along the Thompson River and Kamloops Lake there are outbursts of gas to which attention has been directed recently. Skaters have been in the habit of lighting them in the winter in order to illuminate the ice. An analysis of samples shows it to be natural gas. It is to be found at widely separated places. Various suggestions have been made for the use of this gas. One is that it is made the motive power of an irrigation system for the reclamation of an immense waste district. It is also suggested that there may be oil in the same locality and that the possibility of coal being found is good. That some drilling should be done for the purpose of determining the district's resources, is the general opinion and it is likely that action along these lines will be taken by some of those who have become interested.

**Advice to Prospectors** — J. D. Galloway, resident mining engineer at Hazelton B. C., recently addressed a gathering of prospectors at Usk, a town on the G. T. P. Ry., in which he recommended caution in the sampling of one's own prospect "as it was only human nature for a prospector to be partial and not to pick his sample in conformity with his outcrop, thus deluding himself into putting in work that could better be expended on other veins." It appeared to the speaker that there could be a better understanding between the prospector and the capitalist. The latter

should have the opportunity to develop a sufficiently explored prospect of merit on a long term lease and bond, with a provision for royalty on shipments to apply on purchase price. This would give capital a chance to prove the prospect in from one to four years and, if good, payment could be made and both would be winners. The prospector was advised not to leave his ore and go into expensive crosscuts until after it had been proved on the surface. In many outcrops of minerals in well-defined veins there is a parallelism of veins in a well-defined zone. Many such cases were known in the north country and the miner should prospect along the strike of the veins where richer ore-shoots may be found or extensions of the same ore-shoot. The lowering of freight rates, making it possible to ship ore to the Granby Smelter from Hazelton at \$8 a ton, including treatment charges, opened up possibilities to properties in the Usk district that hitherto have been unable to stand the expense of shipping.

**Smithers** — A. C. Garde, of Prince Rupert, has bonded the Reco Aspen Group of mineral claims, Hudson Bay Mountain, and development will start when the season opens. A cross-cut tunnel will be driven to tap one of the promising showings exposed. The property consists of eight claims and the values are in silver and lead.

**New Granby Concentrator** — The new 1,500-ton concentrator to be installed at Anyox by the Granby Consolidated Mining & Smelting Co. is to be built by company labor and work will commence as soon as the material needed can be assembled. It is expected to be ready for use about February 1, 1924.

**Kamloops** — The Windpass Mining Co., Kamloops District, which is being financed by Messrs. Wood, Trites and Wilson, of Fernie, all of whom are interested in the Premier Mine, has purchased for cash six claims adjoining the group under development.

**Dividend on Silversmith** — The Silversmith Mines Ltd. of Sardon has declared a dividend of 1 cent a share on a par value of 25 cents, which brings the total of the dividends paid by this property to \$150,000. In January, 1921, \$25,000 was paid and in 1922 there was a distribution of \$100,000.

**Trail Ore Receipts** — Ore receipts at the Trail Smelter, Consolidated Mining & Smelting Co. of Canada for the week March 22 to 31 last, totalled 14,001 tons. This makes the receipts for the first quarter of the year 115,925 tons, a considerable gain over the same period of 1922.

Two old shippers are again on the list, namely, the Emerald, a silver-lead property of the Sheep Creek Camp, and the Van Roi, of Silverton. The company's mines have contributed thus far 100,819 tons, most of which has come from the Sullivan Mine.

Following are the details:

| Company                  | Tons  |
|--------------------------|-------|
| Black Rock, Northport    | 81    |
| Company Mines            | 12402 |
| Emerald, Salmo           | 30    |
| Henderson Gp., Smithers  | 50    |
| Knob Hill, Republic, Wn. | 355   |
| Lone Pine, Republic, Wn. | 331   |
| Paradise, Invermere      | 44    |
| Silverhoard, Ainsworth   | 42    |

|                         |         |
|-------------------------|---------|
| Silversmith, Sandon     | 370     |
| Standard, Silvertown    | 32      |
| Surprise, Republic, Wn. | 216     |
| Van Riel, Silvertown    | 47      |
|                         | 14,001. |

**New Seam of Domestic Coal** — The Canadian Collieries (D) Ltd. is doing some diamond drilling near the No. 5 Mine, Cumberland, and a new seam has been struck which, it is said, promises to develop into the best coal for domestic use in the Comax Field of Vancouver Island. This seam will be worked from the No. 5 shaft, which is being driven through rock in order to escape the heavy expense of a new pit-head.

The coal production of British Columbia for the month of March totalled 248,578.09 tons, made up as follows:

|                           |         |
|---------------------------|---------|
|                           | tons    |
| Vancouver Island District | 147,177 |
| Nicola-Princeton District | 21,901  |
| Crow's Nest Pass District | 79,509  |
| Total                     | 248,587 |

**New Rescue Apparatus** — "The Self Rescuer" is the latest production of American scientists for the protection of the lives of coal miners. Its efficiency and its general value for the purposes it is designed to serve are to be thoroughly investigated by the officials of the mines inspection branch of the Mines Department of this province. If it is found that the appliance will protect the lives of underground workers when caught in a foul atmosphere following an explosion, immediate steps will be taken to have the collieries of British Columbia obtain the equipment.

The new instrument consists only of a small tin can, to which is attached a nose clip and a mouthpiece. It weighs little over a pound, is easily disposed of on the person, and can be very quickly brought into use, it is said. It is claimed that it affords absolute protection to the wearer in the atmosphere to sustain life and that it will last for seventy minutes.

**Offences Against Coal Mine Regulations** — As an evidence of his determination that the terms of the "Coal Mines Regulation Act" shall be enforced, Hon. Wm. Sloan, Minister of Mines, has ordered a special inquiry into two recent infractions of the Act. Wm. Wall, of Nanaimo has been appointed under Section 48 of the Act to initiate inquiries into the cases of Thos. Cunliffe, shiftboss in No. 4 Mine, Cumberland, Canadian Collieries (D) Ltd., who has been fined \$10 for firing shots underground without previously examining the working places to ascertain whether or not inflammable or explosive gas was present; and that of Louis Hadevis, coal miner employed at the Nanoose Collieries, Nanoose Wellington Coal Co., who is charged with smoking while at work underground. The breach of the law which Cunliffe was convicted took place on the 28th of February last, about three weeks after the disastrous explosion in No. 4 Mine. He holds second and third class certificates of competency under Coal Mines Regulation Act. Brought before Magistrate Baird at Cumberland he was convicted on his own admission. The case against Hadevis has not yet been brought before the courts. It is stated that he had been suspected by mine officials

for some time of smoking in the mine and was closely watched. As a result it is alleged that the manager caught him with a pipe still warm in his possession. It is asserted that Hadevis appears to have been in the habit of smoking when the Fireboss was firing shots, in the belief that the smoke of the same would carry off the tobacco fumes without them being noticed.

## NOVA SCOTIA

**The Labour Situation.** — The early return of D. H. MacDougall, vice-president of the British Empire Steel Corporation, from Britain and Germany, where he had gone in connection with the affairs of the Company, has brought a feeling of relief in the province, and it is generally believed that labor differences will now be promptly attended to and not permitted to reach the acute stage. The state of uncertainty that has existed for some time is changing for the better, and if the district is not forced into a U. M. W. election by the international executive, better conditions may prevail during the rest of the year. Should an election be forced, the stage is already set for issues that may not be settled without serious trouble. The law of self-preservation is very dear to the executive of District No. 26, and nothing will be permitted to stand in the way of a return to office of these men. With vice-president MacDougall close by, the coal and steel industries should be able to weather any dispute that may arise from this or any other cause.

**A. S. McNeil's Visit to Europe.** — Mr. A. S. McNeil, General Superintendent of the Dominion Coal Company, Glace Bay, has returned from a visit to the British and Belgian coal mines. Mr. McNeil was greatly interested in the methods of mining carried on in the English and Scottish coal mines. He inspected over twenty collieries, and went into the workings to get first-hand information. He speaks very highly of the courtesy and kindness of the mine officials he met. He was given every opportunity to see and to know what was going on in and around the collieries visited.

The longwall system of mining especially interested Mr. McNeil, and so far as he could in the short time at his disposal, he studied the different phases of this method, which is almost universal in British coal mining. He marvelled at the complete control of the pressure of superincumbent strata. It matters little whether this pressure is exerted on a rock roof of strong limestone, or one of softer material such as shale or soapstone. When a break is necessary to lighten the overhead burden and save the longwall faces, it is brought about with a certainty and regularity that only long years of experience and training on the part of the mine officials and miners could effect. The building of longwall packs in the proper places with the right kind of material (wood or stone); the drawing of all timber from the gobs or waste workings so that a good fall would take place; — all is part of the method, and is carefully carried out. Superintendent McNeil was fortunate enough to see a section of the longwall face where the packs and gob timber had been left in against instructions, to the detriment of the system. The roof rock was falling in, right up to the face. It made a noise like heavy thunder as it broke its way down. Crawling up in a low space on hands and knees after the official in the lead, he had a most uncomfortable feeling. Such cases of neglect are

rare, but when they do occur those responsible are usually dealt with in a summary manner. In several of the mines he entered there were seams very much like some of the Cape Breton coal seams now being worked. The overlying strata and the thickness of the seams were much the same. The method of mining, however, was entirely different. But whether the method of longwall mining can be applied to the Cape Breton seams is as yet problematical.

To change the method of mining requires specially trained workmen, and these are not to be found in Nova Scotia. Any change to be made must come very gradually. It is easier to change the method, if the structure of the strata permits, than to change the miner, and without this there would be absolute failure.

One of the interesting features seen by Mr. McNeil was that of the use of steel props. These were used in a mine with a large daily output, and yet such was the skill of the miner in drawing them, that scarcely one dozen props were lost in a whole month. When we consider that over two thousand props are put into one of our large mines each day, we can understand the difference in the cost of roof support.

Another feature of interest was the longwall conveyor and loader. Those who have knowledge of the longwall system know that in thin seams the mine car cannot be taken along the face, and all coal must be shovelled first to the road head and there filled into the mine car. This entails a lot of extra shovelling, and causes much breakage of coal, and of course reduces the output per man. The work is laborious and distasteful to handpick miners. The mine conveyor has done away with this heavy work, and is in almost general use. Here and there a mine manager may be found sticking to the old system, preferring to "bear the ills he has than fly to those he knows not of"; but such officials are few and far between. The conveyor plays a large part in the loading of coal in the mines of Britain and the Continent.

It took upwards of ten years to introduce these labor — and coal — saving machines. If they did nothing more than save the large cost entailed in brushing each separate roadway they did very much; but they also made coal mining easier and greatly reduced the amount of fine sizes of coal sent out of the mines, and reduced the cost of mining. The conveyor is established, however, in the British mines, and we are quite safe in making the statement that should they be taken out of the mines, the miners would cease to work until they were put back.

The housing conditions were also studied, and while Supt. McNeil saw many fine colliery villages, in some respects excelling those of Nova Scotia, he saw many others that were not up to our standards. To show how British miners live, Mr. McNeil was treated to a very nice supper in a miner's house. The house was picked out at random and the family were just sitting down to supper when, in his own pleasing manner, Mr. McNeil asked permission to join them. The food was excellent — "hamely fare", Burns would say. The table was clean and so was the house and all that was in it, and the supper was very much enjoyed.

Having met the British miner at his work underground, as well as in his home, Mr. McNeil has a

deepened respect for him and well understands how, when he comes to this country, he misses the social life of his native land, which fills a want no new country like Canada can supply. For the British coal mine official he has developed warm feelings and great admiration.

**Labor Politics in Halifax Assembly.** — "Every Deputy Inspector shall be elected each two-year period by the employees working below ground in the jurisdiction over which he shall have supervision." This amendment to the Mines Regulation Act of Nova Scotia was the subject of discussion in the local Assembly a few days ago. Knowing that their case was weak and required bolstering, the Labor members, who sponsored the Bill, contended that all Deputy Inspectors of coal mines should be holders of the Mine Manager's Certificate. This, on the face of it, does not seem unreasonable, but when the same men in the same breath advocated the appointment of Mine Inspectors to such responsible positions by popular ballot all confidence in the sincerity of their plea was destroyed. When special reference was made to an inspector in the Glace Bay district who, while without a certificate, is nevertheless, a man of known ability and high moral character, the whole motive was disclosed. Premier Armstrong, referring to this inspector, stated that he was one of the best Deputy Inspectors in the Province. This ended the debate, and no doubt proclaimed the demise of the Bill.

**The Late Alexander Dick.** — The news of the sudden death of Alexander Dick, General Manager of the Coal Sales Dept., British Empire Steel Corporation, came with a great shock to his many friends in Nova Scotia. Like many another Nova Scotian, Mr. Dick had worked his way up from humble beginnings. He was for a time in the colliery office at Springhill. From there he went to River Hebert as manager of a coal mine. Afterwards, he went to the Canadian West in quest of a more precious mineral than coal. When Cornelius Shields became general manager of the Dominion Coal Company, Mr. Dick came in with him as general sales agent. He was most successful in business, and during his time there was a rapid expansion in the coal industry of the province. He was of a genial, happy temperament. He made friends with everybody, but never forgot the old ones. This was equally true among the mining population as on others of more lofty social position. The writer first knew him in Springhill, when he had just passed the age of twenty. At that time he attended the night school of "Jake" Johnston of life insurance fame. After school hours, a large part of the evening was filled in by listening to the stories of the teacher. "Sandy" (for that was the familiar name by which he was then known) became a very apt pupil in this art, and when in congenial company, his stories, told in his own winsome way, reached both the heart and the intellect. He was, indeed, very pleasant to meet, and possibly after all this shedding of warm sunshine everywhere he went was not the least of Mr. Dick's attainments. At such a time as this the loss to his beloved province and to the coal industry of such an able official is great indeed.

Mr. Dick was twice married, his first wife being Margaret Hall, eldest daughter of the late William Hall, ex-manager of Springhill colliery, and his second wife, Nellie Doyle, daughter of Joseph Doyle, Dublin, Ireland.

### RESEARCH ON COAL

A study of the desulphurization of coke by steam is one of the four important problems undertaken this year at Carnegie Institute of Technology, in co-operation with the U. S. Bureau of Mines. Each of the problems was suggested by an Advisory Committee of coal-mine operators and engineers. The research work is a continuation of the co-operative plan inaugurated last year by the Advisory Board, the Bureau of Mines, and Carnegie Tech. The other investigations being conducted are the correlation of coal beds of Western Pennsylvania through their microscopic constituents, with the Pittsburgh Bed as the basis of study; a fundamental research on the corrosion of alloys in various media; and a study of low-temperature tars from typical Pennsylvania coals, with the Pittsburgh Bed as the basis of study. As was the case in connection with the investigations conducted during the preceding year, Carnegie Tech. will publish the results of the studies soon after completion an announcement.

### DESULPHURIZATION OF COKE BY STEAM

In the course of laboratory experiments in the desulphurization of coke by steam, being conducted at the Pittsburgh Pa., experiment station of the Bureau of Mines, steam tests at atmospheric pressure for the removal of sulphur from chunk size coke have been finished, with encouraging results. Combined sulphur as FeS, FeSO<sub>4</sub>, and free sulphur (not including solid solution sulphur) in Ohio coke was reduced from 1.38 to 72%. The solid solution sulphur was not affected, but it has been shown that this has very little effect in contaminating sponge iron in the blast furnace. In Illinois coke, .62% sulphur corresponding was reduced to .48. Clairton coke low in sulphur was reduced from .29 to .17%. Sulphur in a sample of gas-house coke from Philadelphia was reduced from .81% to .60. These results were obtained without application of vacuum which may reduce still further the amount of sulphur. Very little steam is required - three grams of steam per gram of coke per hour were employed, which is a big excess. Iron will be heated in contact with the treated coke and the transfer of sulphur determined.

### HYDROPLANES FOR FOREST PATROL

The Canadian Department of National Defence has placed an order with the Canadian Vickers here for six hydroplanes. These, it is understood, are mainly to be used in forest patrol and fire prevention work. The planes will be manufactured in Montreal.

**CHEMIST** — Some assaying and practical mining experience, also thorough business training, desires position Mine-mill or Smelter. Adaptable; efficient good health. Reply; Box 573, Canadian Mining Journal, Gardenvale, Que.

### PURCHASE OF GOLD ORES

The attention of prospectors and others is drawn to the provision in the Mining Act of Ontario authorizing the Department of Mines to purchase parcels of gold ore taken out by prospectors and others in developing or working mining claims. Arrangements have been made by which such parcels of gold ore, whether large or small, will be accepted by the Temiskaming Testing Laboratories at Cobalt, and paid for according to the schedule provided for the purpose. The Laboratories are operated under the auspices of the Department of Mines.

This offers a first class opportunity for testing the value of ores on a large scale, and also of turning ore of good quality into money for carrying on further development work. By special arrangements, on less than carload lots, freight rates on the T. & N. O. Railway are reduced 50 per cent.

The Laboratories are also equipped for working out the best methods of treatment for gold or silver ores of a refractory or unusual character.

Full information as to treatment charges, schedule of payments, etc., can be obtained from the undersigned, or from A. A. Cole, Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

Our other lines of Manufacture are Wire Cloth for all uses, Perforated Metals, Wire Pulp Mats, Clothes Lockers, Machinery and Window Guards, Pulp Mats, inquiries solicited.

## Eliminate Hot, Dusty Working Faces

In driving entries or working thin veins and pockets, the main ventilating system seldom serves the out-of-the-way places.

The air at remote working faces is usually hot, humid and dusty. Production is slow and costs high.

Canadian Sirocco Ventilating Sets, used with canvas tubing and moved from place to place as required, will bring fresh air to these troublesome spots. No matter how hot and dusty, or how far removed from the main shaft or tunnels, they can be ventilated and cleared of smoke, gases and dust, by means of these auxiliary ventilating units.

Write for bulletins showing how you can remove the dangers of dust and gases and lower production costs.

**Summary Report of the Mines Branch, 1920.**

The Mines Branch maintains the following laboratories in which investigations are made with a view to assisting in the development of the general mining industry of Canada:—

**Fuel Testing Laboratory.**—Testing value of Canadian fuels for steam raising and production of power gas; analyses, and other chemical and physical examinations of solid, liquid and gaseous fuels are also made.

**Ore-Dressing Laboratory.**—Testing of Canadian ores and minerals, to ascertain most economical methods of treatment.

**Chemical Laboratory.**—Analysing and assaying of all mineral substances and their manufactured products. Copies of schedules of fees, which are slightly in excess of those charged by private practitioners, may be had on application.

**Ceramic Laboratory.**—Equipment is such that complete physical tests on clays and shales of the Dominion can be made, to determine their value from an economic standpoint.

**Structural Materials Laboratory.**—Experimental work on sands, cements and limes is also undertaken.

**Applications for reports and particulars** relative to having investigations made in the several laboratories should be addressed to The Director, Mines Branch, Department of Mines, Ottawa.

**Summary Report.** The annual Summary Report of the Geological Survey is now printed in parts. Applicants should, therefore, state what particular geologist report is required, or what subject they are interested in.

**Memoir 108.** The Mackenzie River Basin, by Charles Camsell and Wyatt Malcolm.

# CALYX CORE DRILLS

give the most accurate information possible to secure regarding mine property — a complete record of the texture, structure and composition of the overlying, underlying, and ore-bearing strata. This information is essential to determine the most efficient and economical methods of developing and operating.

The CALYX CORE DRILL penetrates any material from the softest clay to hardest rock.

It will give cores from 1½ in. to 16½ in. and will penetrate to a depth of 4000 ft. It drills straight holes.

It uses "CALYXITE," a chilled steel shot, in place of diamonds, thus reducing initial cost and dispensing with the services of an expensive diamond setter.

**It Must**

**Be Pure**

The purity of the oxygen and dissolved acetylene used in welding and cutting operations has an important bearing on the result.

Only gases of extreme high purity will do a clean, satisfactory job, economically. That is why tests made by chemists and engineers show that both Dominion Oxygen and Prest-O-Lite Dissolved Acetylene have the highest rating of purity.

Both of these products are invariably maintained at a higher

mark of purity than is usual for commercial use—an elaborate series of tests in our plants assures this uniform quality.

It is certainly more economical for you to buy the purest products when the price you pay is the lowest obtainable compared with other commercial oxygen and dissolved acetylene price lists.

So why not take full advantage of the saving offered to you by Dominion Service?

**DOMINION OXYGEN COMPANY LIMITED.**

# MORSE CHAINS

A few of the Morse chains in use at the Raymond Lead plant

Using chain drives speeds up production, cuts belt expense and overtime wages and operates with practically no repairs.

Write for Booklet

CANADIAN AGENTS

**Jones & Glassco, Regd.**

MONTREAL, TORONTO.

O. W. Ludwig, Plant Superintendent of the  
Raymond Lead Co., Chicago, says:

"Thirteen years of service without a repair is our experience with two 100 H.P. and ten 20 H.P. Morse Silent Chain Drives.

"When we moved into our present plant thirteen years ago, we installed the present Morse equipment of silent chains for our two lead mills and ten hydraulic pumps. We had always previously used leather belts, but not without considerable trouble. For instance, if the operator was not careful—and gave the motors too great a load, the leather belt would slip and in some cases burn out. While with the Morse Chain Drive we overload them at times up to 15 H.P. without the slightest trouble.

"When we used leather belts on the hydraulic pumps, if a pump packing suddenly gave way, the water would squirt all over the pump as well as adjoining pumps, causing the leather belts to get wet. This often necessitated a shut-down on 3 to 4 pumps to dry out each belt, thus causing a loss of time by the men, which resulted many times in paying overtime to catch up on the work. Of course, with our Morse Chain Drive we have no such trouble—this positive drive prevents slippage and is not affected by water.

"Leather belts lasted us 2 to 3 years at the most, while our Morse Chain Drives have already lasted 3 to 4 times that long and seem good for many more years. So Morse Drives have cut our expense materially, speeded up production, cut out overtime wages and saved floor space, for they operate on shorter centers."

# Ontario's

# Minerals

PROVINCE OF ONTARIO

DEPARTMENT OF MINES

HON H. MILLS, Minister of Mines

## Mineral Areas.

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favorable for the occurrence of minerals, 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver mines of Cobalt occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

## Economic Minerals.

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario:—actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluor-spar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, portland cement, brick and tile, meet every demand.

## Mineral Production.

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1921 to be worth \$48,128,387, of which the metallic production was \$27,574,202.

The following figures show the rapid growth of Ontario's mineral industry by five-year periods since 1891:

| Year.         | Value.      | Year.         | Value.       |
|---------------|-------------|---------------|--------------|
| 1891 .. . . . | \$4,705,672 | 1906 .. . . . | \$22,388,383 |
| 1896 .. . . . | 5,235,003   | 1911 .. . . . | 41,976,797   |
| 1901 .. . . . | 11,831,086  | 1916 .. . . . | 65,303,822   |

## Dividends.

Dividends and bonuses paid to the end of 1921 amounted to \$23,140,734 for gold mining companies, and \$84,388,185 for silver mining companies or a total of \$107,528,919.

## Mining Regulations.

A miner's license costs \$5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of \$2.50 or \$3.00 per acre, depending on location in unsurveyed or surveyed territory.

## Assay Office.

The Provincial Assay Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

## Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

# Serving Canada's Mining Industry

It is many years since The Imperial Bank of Canada, recognizing the importance of the Canadian mining industry and realizing the need of banking facilities for those engaged in its development, first opened a branch in Northern Ontario.

Since then the Imperial Bank's service has gradually extended until the mining interests in the rich area between North Bay and Hearst are now linked up by a complete chain of 12 branches.

This Bank's service to the mining industry is not confined to Northern Ontario alone. In all the mining areas throughout Canada the "Imperial" is rendering a valuable and complete financial service.

### THE RIOTS AT THETFORD

After a week of disturbance and idleness, the miners of the Asbestos Corporation in the Thetford asbestos district of Quebec have returned to work. The good offices of several local authorities were used during last week to bring together representatives of the miners and the company. Conferences were held in Sherbrooke and grievances aired and discussed, with the result that the miners are now at work in the pits.

While it has not been announced publicly what the temporary terms of settlement involve or what is back of the trivial complaints the miners brought forward as justification for their precipitate action, the general features of the case present no enigma. The asbestos district of Quebec has never yet become closely identified with the mining industry of Canada, in its personnel. This is, with minor exception, true of its engineering staffs, and it is completely true of its mine workers. There is no ebb and flow of miners between the other mining camps and Thetford. The asbestos district is self-contained — and self-sufficient.

An inevitable result of this isolation is that there have developed among the mine workers of the asbestos district habits peculiar to themselves. Some of these free-and-easy habits are more typical of the farm than of the industrial community and are noticeable to any visitor in the camp. The older generation of workers, coming mostly from the farm, inaugurated these habits, and so long as they worked faithfully and consistently as they would on their own land, these peculiarities did not interfere with their efficiency. It has been noticed of recent years, however, that the younger generation of workers, while retaining the prerogatives of their elders, have been inclined to drop the old habit of faithful service to their employers. The discipline exerted in all modern industrial establishments is the only known cure for such laxity in duty. Colonel MacNutt commenced to apply the ordinary disciplinary methods in order to regain the lost efficiency of his miners, with the result last week of riots and strike.

There is no doubt that, if Quebec is to retain fully her present ascendancy in the asbestos markets of the world, her mines and mills will have to be operated with more efficiency and economy than at present. A number of other producing areas throughout the world are pressing every advantage they possess in order to cut into Quebec's trade. The principal part of the cost of making asbestos ready for export is

labour. To ensure the continuance of production from our asbestos mines and mills, the labour that mans them must have a maximum of efficiency. At present this labour is notably inefficient, having declined sadly in quality during recent years. The late disturbance may prove to be a blessing in disguise, by drawing attention forcibly to the one feature that, above all others, will be the reason for Quebec's continued predominance in asbestos production — efficient and well-directed labour.

### RESULTS FROM THE COAL CAMPAIGN

Our Nova Scotia correspondent records today an active step taken by the provincial government in Halifax with a view to increasing the useful production of the province's coal measures. The present interest in bituminous coal as domestic fuel, via the by-product coke oven, promises a profitable outlet for Nova Scotian coal much larger than any available at present. The officers of the British Empire Steel Corporation are evidently investigating seriously, and with some success, the feasibility of putting their coal on the Montreal market as coke, in competition with anthracite. If this is a paying proposition, the question immediately arises as to the quantity of coal available in Nova Scotia. This question the Mines Department in Halifax has undertaken to answer.

In his announcement at the annual meeting of the Canadian Institute of Mining and Metallurgy in Montreal last March, Dr. Charles Camsell announced, on behalf of the Dominion Fuel Board, that it had decided to direct its attention to three major problems:

- 1.—To determine the economic maximum production of which the Nova Scotian coal fields are capable.
- 2.—To investigate the possibility of converting bituminous coal into coke for domestic use.
- 3.—To demonstrate the eastern limit to which Alberta coal can be shipped profitably.

It is a notable fact that each of these three important problems has now been tackled seriously by private interests, and that in addition the Ontario government has interested itself actively in securing a trial shipment of coal from Alberta. The principal credit for this general and active interest in our country's fuel problem must be given first to the prompt and accurate diagnosis of the case provided by the Dominion Fuel Board, and secondly to the judicious and effective publicity afforded their findings.

It is highly satisfactory to find that the provincial governments and private companies have been impelled to undertake these investigations. In each case they are the authorities or persons directly concerned, and therefore they are most likely to pursue their investigations to a conclusion and to apply them in practice as far as is feasible.

It might appear to the superficial observer that, with these three major problems now in the hands of competent local authorities and with a number of minor problems likewise in good hands, the work of the Dominion Fuel Board and their corps of voluntary advisers was finished. This is far from being the case. The fight for the use of Canadian coal in Canada is only well begun. The Dominion Fuel Board has provided effective leadership for the forces of progress, and has mapped out a plan of campaign that promises to lead on to victory. But the fight is bound to be long, and there will be, doubtless, local set-backs. Without a leader, mis-directed effort, often at cross-purposes, jealousy, bickering, and finally failure or disaster are bound to ensue. With a continuance of the present competent leadership, we shall succeed in applying to the utmost the ideal, "Canadian coal for Canada."

#### "PREVENTIVE GEOLOGY"

The province of Alberta has an active, though small, geological survey department in the form of a section of its Scientific and Industrial Research Council, closely identified with the University of Alberta. Direct evidence of the vigour of this department is afforded by the report recently issued, "An Occurrence of Iron on Lake Athabaska," by Professors John A. Allan and Alan E. Cameron.

In 1921 reports were circulated by Messrs. E. A. and N. C. Butterfield that they had located on the north shore of Lake Athabaska vast deposits of iron ore of exceptional purity. The possible importance of such deposits, even in that remote region, in conjunction with the coal of Alberta prompted the provincial government to investigate the alleged discoveries, although they are east of the interprovincial boundary, in Saskatchewan. The examination, made during the summer of 1922, confirmed previous reports of official explorers, to the effect that there is no high-grade ore available in the area designated, nor is there any likelihood of a concentration of ore beneath the surface. A large part of the area claimed by Messrs. Butterfield to be high-grade ore was found to be merely iron-stained quartzite and other rocks.

After the officers of the Scientific and Industrial Research Council of Alberta had returned from the field last summer, their conclusion as to the true nature of the alleged discoveries of iron ore was made available promptly to the public and was circulated

widely. Now we have chapter and verse for the conclusion, in the form of this 33 page report. The result is negative; but the expense of this little official expedition, which consumed less than three weeks in its geological examination, may have prevented the senseless dissipation of very large sums of money.

#### THE POWER MONOPOLY

The Hollinger has secured the rights to the Long Sault water power on the Abitibi. Apart from that, the present monopoly of hydro-electric power supply for the various camps of the northern gold district of Ontario and Quebec has been preserved by the lease last week of the Quinze power to Mr. Alex. Fasken and his associates. This group control all the developed powers now serving the mining camps, with the exception of that of the Great Northern Power Company, which is too small a power to compete seriously with the monopolists.

It is very satisfactory to know that the provisions under which the Quinze power has been leased to Mr. Fasken will result in the immediate development of a part of it. All the gold camps from Porcupine eastward are thus assured of sufficient power for their requirements from 1924 onwards. Should the gold belt develop to dimensions even approaching those of the Rand, more of the power of the Quinze River would have to be put to use; but that time is not yet in sight.

The price of power to the gold mines is likely to remain high, as at present. The annual rental of \$80,100, in addition to the further annual payments specified the terms of lease, might seem to be onerous. However, when one remembers that this large power on the Quinze will provide cheap power compared with the present smaller installations, and that, safely protected by a monopoly of the supply, the current rates for power are more than likely to be kept at their present high level, it is not hard to understand Mr. Fasken's willingness to meet the terms for which he has contracted.

Luckily there is virtually no competition in the market for gold. The struggle of miner and metallurgist is to reduce the cost of producing the gold below its market value. The Hollinger will have the benefit of power at cost from its prospective Long Sault plant, and will be able to treat ore at a much lower cost than at present. The rest of the mines will be dependent upon the plants controlled by Mr. Fasken and his associates. These men are much too shrewd to prevent the laying of golden eggs by the goose hidden in each gold mine; they will doubtless preserve a judicious balance between their prerogative of keeping up the price of power and the stimulus that cheaper power will provide to mining. Consequently we can look forward with confidence to a permanent and adequate solution of the power problem.

### GREAT BRITAIN'S FINANCE

The British financial year ended on the 31st of March. It had been estimated by the late Chancellor of the Exchequer, Sir Robert Horne, that the national accounts for the fiscal year would show a surplus of between \$30,000,000 and \$35,000,000. But, instead of any such relatively small surplus as that, the actual surplus is one of over \$500,000,000.

This big surplus is mainly attributable to large reductions in expenditures, the chief savings being under the head of civil services and defence services. It is not fanciful to hope that the fact of Great Britain's making the most drastic cuts in Civil Service expenditure with such a satisfactory financial result for the nation at large will not be lost on other countries. We should be greatly surprised if the pruning-knife could not be applied vigorously to Civil Service expenditures in this country and with results equally gratifying to the national purse.

Naturally enough, the question uppermost in people's minds in Great Britain is that of the use to which the present Chancellor of the Exchequer, the Rt. Hon. Stanley Baldwin, will put this large and welcome surplus. The income tax in Great Britain is five shillings in the pound, which means that the ordinary taxpayer has to pay a quarter of his income in direct taxation of this order — people with large incomes have to pay at a far higher rate than that — besides being mulcted in various other ways, and notably in very heavy death duties on his decease. Thus the Chancellor is sure to be bombarded — in fact, is certainly being bombarded now — with supplications for a substantial reduction in the income tax. On the other hand, as he will have to meet the interest on the debt to the United States, and also make a payment on the sinking fund in respect of that debt, it is quite possible that he may decide to maintain the income tax at its present rate. But it is at least a matter for argument whether it would not be a better course to attempt to stimulate trade by a reduction of taxation rather than to maintain the national taxation at its present figure, particularly in view of the widespread unemployment in the country.

This will be decided by the time these lines are in print. But citizens of other countries may well note with admiration the proof afforded, in this large surplus, of Great Britain's remarkable financial strength. The truth seems to be that the most appalling financial burdens cannot avail to hold the British down. Their trade has not expanded to any very large extent during the past year. But if they cannot get a surplus one way, they will get it in another. If they cannot get it by national earning, they will save it by national retrenchment. That is the moral of British financial methods, and it is one which we in Canada may well lay to heart.

"The thirty-first annual meeting of the Nova Scotia Mining Society — and the fifth annual meeting since the N. S. M. S. became one of the milch cows of the Canadian Institute of Mining and Metallurgy — was held in Halifax on the 10th and 12th inst." So says, the "Maritime Mining Record" of Stellarton, Nova Scotia, in its issue of April 25th. The spirit of this utterance is not worthy of the veteran editor of that publication, and we hope that it belies the spirit of the mining engineers of Nova Scotia. The implied financial relation between Mining Society and Institute is falsely stated. The fact is that for the four years 1918 to 1921, the average contribution to Institute funds by members of the Nova Scotia Mining Society was \$7.00, against \$8.63 by members outside Nova Scotia. We hope that a clear view of the mutual benefit obtained through the amalgamation of the provincial Society and the national Institute will not become obscured through any trivial misunderstandings.

Literally thousands of travellers have passed on the winter roads into the gold district of Northwestern Quebec during the last few months. The favourite route has been from Dane, on the Temiskaming and Northern Ontario Railway, which passes by the Argonaut Mine. Among the havens of refuge along this route, none has been appreciated more than this camp where Mr. J. W. Morrison and his aides have welcomed all comers and entertained them right royally, in true north country fashion. The prospectors of the north have developed a very warm regard for the Argonaut and its manager.

### MATACHEWAN

The waters at Matachewan  
 Rippled, as kissed the rising sun,  
 While down below the rapid's fall  
 The gliding eddy made its run.  
 The reek from morning fires swung low  
 The time was two score years ago.  
 The morning mists hung in the bay,  
 Screened by the forest growth on shore,  
 While down the pathway from the hill  
 The factor's daughter slowly bore,  
 For water to the river's strand,  
 The swinging bucket in her hand  
 The Factor's Caledonian pride  
 Refused her Indian lover's prayer,  
 With shaded eyes she gazes down  
 As though to find his image there,  
 The weaving smoke begins to trace  
 The features of her dear one's face,  
 When from the mists along the shore  
 A bark comes gliding to her feet,  
 His messenger to bear her hence  
 To where he waits in sure retreat,  
 By Shakakoba's shaded shore  
 The lovers meet to part no more.

\* \* \*

The factor long has left the stage,  
The lover husband too has gone;  
The maid who gazed with dreaming eyes  
Is now a matron left alone;  
And just as changed from days long gone  
Is all around Matachewan.

A roadway spans the rapid bright,  
Carrying the miles of gleaming lines,  
That bring from harnessed Kageawan  
The magic power to speed the mines;  
And syrens pierce the silence through  
Where once were moose and cariboo.

The river bright bears on its breast  
The power boat with trailing barge,  
While vibrant engines throb and strain,  
The nation's treasure to enlarge,  
And searred with fire is forest fair  
Where drum of grouse once stirred the air.

But still at Fort Matachewan  
The sunlit waters surge and gleam,  
While from the hill, in Autumn's mists,  
One looking far adown the stream  
In fancy sees the bark of gold  
That bore the maid in days of old.

H. E. McKEE.

Some of our readers will recognize the characters of the story above. The factor at Fort Matachewan, Mr. Faries, whose daughter married young Dokis, preceded Mr. Steve Lafraicain, known to all who have travelled the Montreal River. The Indian messenger, Round Eye, died only recently at Elk Lake. "Kageawan" is the Indian name for Indian Chutes, whose power is now being developed. "Shakakoba" is the trading post on the Sturgeon River where the lovers "lived happily ever afterward."

## ROUTES TO THE QUEBEC GOLD FIELD FROM THE NORTH

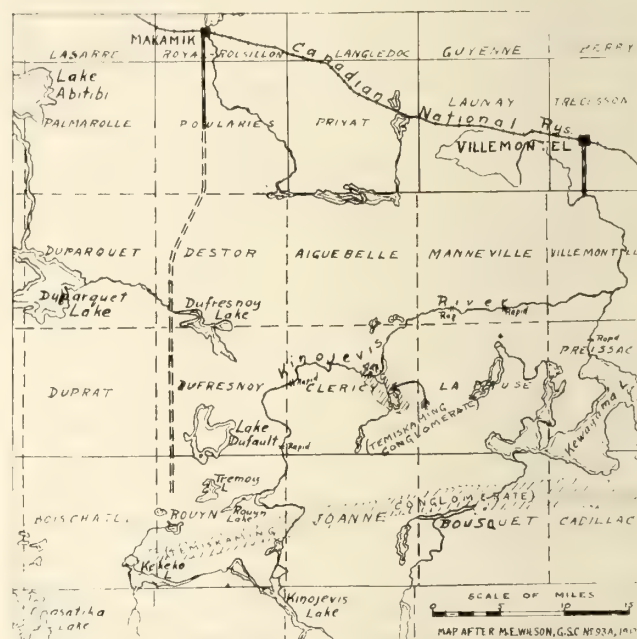

Four weeks ago there appeared in these pages a description of the routes to the Rouyn gold field area from Lake Temiskaming. A description of the routes from the Canadian National Railways to the north of the area has been given by Messrs. Leon Gobeil and R. Audet, inspectors of roads for the provincial government, who have lately completed a road survey southward from Makamik, in "La Presse."

At Villemontel, a station on the Canadian National Railways 12 miles west of Amos, commences the route that was used last year by many entering the new gold field. It will be available for use immediately after the lakes are clear of ice. A colonization road, already constructed, runs twelve miles southward from the station to the Kinojevis River. From here the river is navigable for canoes down stream to Rouyn Lake. There are a number of rapids and portages on the Kinojevis River in this stretch of 35 miles, which make the use of motor boats impracticable.

From Makamik, 40 miles west of Amos on the Canadian National Railways and 35 miles in a direct line

north of the gold discoveries in Rouyn township, there is a road already built for a distance southward of nine miles. The two road inspectors projected this road southward for the remaining 26 miles, and found that a first-class location, with no grades over 10 per cent and with comparatively easy construction, is available throughout the whole distance.

The land of Poularies township for a distance of nine miles from the railway is good agricultural land. Here it changes, outcrops of rock and stretches of swamp appearing, while for several miles the road location crosses sand and gravel plains, most suitable for road construction. In Destor township the location swings slightly to the west, to avoid Dufresnoy, Dufault and a number of smaller lakes. It terminates at Lake Hérey, in the northwestern part of Rouyn township, where active mine development is under way.

The surveyors note that, although the road location in Dufresnoy is level, the surrounding ground is much broken with rock exposures. In the valleys round Lake Dufault there is good farming land.

This proposed road from Makamik southward would take two years to complete. Its purpose would be partly to aid colonization and partly to afford access by the shortest possible route from existing means of transportation.

There are thus two water routes already available for use into the new gold area, a land route from the south which it has been decided to construct, and a land route from the north whose construction is proposed. The route from Ville Marie on Lake Temiskaming will be served by automobiles and motor boats, and is slightly over 100 miles in length. The route by road from North Temiskaming to Lake Opasatika, a distance of 27 miles, thence by water for 20 miles, and again by road for 14 miles, will have a total length of 61 miles to the present gold prospects in the northwest corner of Rouyn township. The canoe route from Villemontel is as stated above, 47 miles long, including the twelve miles of road, and the proposed road from Makamik is 35 miles in length.

# Playing the Great Woods Game - I

HINTS TO A NEW PROSPECTOR FROM AN OLD ONE

BY TOM SAVILLE

Hudson's Bay Bill, Prospector-Hunter, pulled into the trading post at Gogama, which lies about a hundred miles as the crow flies to the north of Sudbury. Bill had started that morning with his dog team from his hunting camp on the Grassy River—Ka-mi-skwa-pi-ka, the Indians called it, but Bill called it "Red Rock" for short. The sun was still high when he drove into the Post. It was almost the end of March and Bill figured this would be about the last chance he would have to get his mail before the break-up. He also wanted to renew his prospector's license before the first of April.

Bill anchored his huskies by tying the bow line of his toboggan to a big pine stump and then entered the Post with his pack of furs, after a lot of "Bojou, Bojou," and shaking hands all round. The Factor tells him—"Bunch of mail for you, Bill,"—and sure enough there is. Toronto "Globes," a bunch of "Literary Digests," some "International Book Reviews," Department of Mines Reports, geological maps, Bulletins of the Canadian Institute of Mining and Metallurgy, a pile of "Canadian Mining Journals" and a few letters.

Bill soon completes trading with his furs with the representative of "The Gentlemen Adventurers Trading into Hudson's Bay," incorporated A. D. 1670, whose motto is, "A skin for a skin"—or in other words, an even break. After getting a few little things that he has run short of, he heads his dogs for his camp, which is located just across the lake. He finds his camp just the way he left it in the fall. Soon he has a good fire going and the kettle boiling and after supper when the huskies are fed and all his chores are fixed up for the night and he has kicked into a change of foot-wear and his beaded moccasin slippers, he wades into his mail. The last letter he opens up is from a couple of young fellows who have decided to break into the great Prospecting Game. This letter interests Bill and he goes over it again. Let's go over it with him.

Toronto University,  
March —

Hudson's Bay Bill,  
Muskeg-Gogama, Ontario.  
Dear Bill,

My class-mate and I have decided to spend the summer up north, prospecting for gold. We happened to see by the "Canadian Mining Journal" that you were a prospector and being inexperienced ourselves, we are taking the liberty of writing you for information and advice. We are both going through for mining and this past winter have read up a good deal of geology and mineralogy and have been over to the Mines Department and obtained the reports and geological maps of the different mining camps of the North. We are taking a blow-pipe outfit and the necessary chemicals to make field tests. We are also taking along a small mortar and pestle for panning. What do you think of the Quebec country? Assuring you that any information, advice or suggestions will be appreciated by us.

Yours sincerely,  
A. Hustler.  
Will Makegood.

## Hudson Bay Bill's Reply

Muskeg-Gogama, Ont.  
March —

A. Hustler and Will Makegood,  
Toronto University.

Gentlemen:

You do me proud by writing me. Sure, I will be glad to tell you what little I know about this Prospecting Game. You done well to get them reports and geological maps from the Department of Mines. That tells me you are on the right trail, and you will profit from the other fellow's experience, I am also glad to learn that you are taking along a blowpipe outfit and a few chemicals to make field tests. There are deposits of minerals and metals other than gold in this North Country and the little blowpipe and chemicals for field tests are sure to hound hell out of them. I would suggest that if you can manage it at all, you make a trip into Porcupine or Kirkland Lake camps before you take the field; it is well worth while.

Now about your outfit. I won't say a word about your grub because nobody knows your capacity and tastes better than you do yourselves. But take along lots, because the wear and tear of packing across the portages and paddling that loaded seventeen-foot guide's special canvas-covered canoe is sure considerable and hard on grubstakes. Then again you are reasonably sure of catching, on your troll, enough fish to keep you going. Take along an extra maple paddle and every man his own camp axe.

Now about your tent; get a 7 by 9 A tent, one that the ridge pole pulls right through and with sleeves that tie tight round the pole to keep the melodious moskitty where he belongs at night—on the outside. You will do well to get an extra yard of duck sewed on the wall of your tent (they are all made too low), as that will give you lots of lap underneath, which will answer the purpose of a ground cloth. And while you are getting your tent fixed up, you might as well do it right; get a piece of fine netting or cheese-cloth sewed right across the door with lots of over-hang—and then you've got a Home.

Next is a tarpaulin—about 8 by 10 is a handy size—to throw over your stuff (sometimes it rains even on a Prospector) or to use as a lean-to for a flying trip and so will save you pulling your tent and outfit down. We always take along for an occasion such as that a home-made canopy or moskitty camp. You can get them already made up; but get the large size.

I suppose you both have a good, big double woollen blanket apiece. And if you haven't got a reflector included in your cookery outfit, put one in; you will find you need it. Some are made of aluminium and are very light. They take the place of a stove and there is a little pan that goes with the outfit. You can bake your pork and beans, bread, bannock, fish and bacon, or roast your venison or moose meat (what's that?!). Anyway, we fellows who live in the woods like to see a reflector included in an outfit where the cooking has to be done round the the camp fire.

I presume you both have a packsack and a tump line each. A light grub hoe is also handy for stripping and pulling the moss off. A light haversack for your note book, compass, maps, samples, lunch, and so on, is also a part of a prospector's outfit.

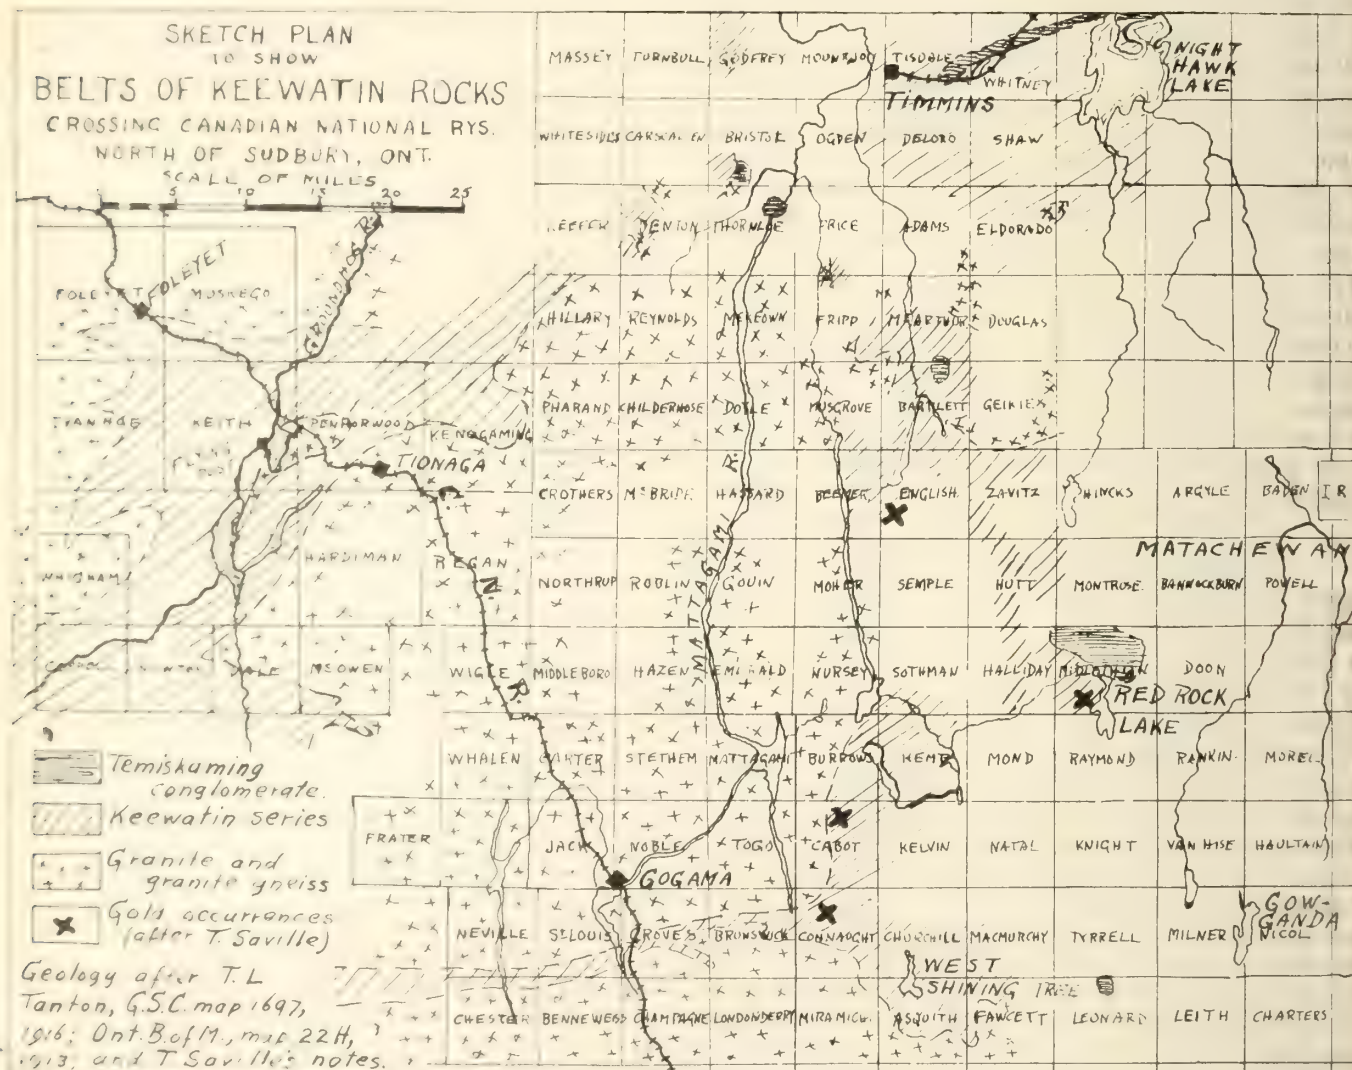

That about completes your outfit. The rest you will rustle for yourselves, but I would suggest you take along that old Mackinaw coat; we all wear them in the cool of the evening and when paddling or packing in the rain.

Now about prospecting for gold. You will be surprised how simple it all is. By making a trip through the established gold camps and reading up the reports and studying the geological maps of the Departments of Mines, you fellows can talk volcanics, shear zones, contacts, porphyry intrusions, and the Timiskaming series, just as if you had been camped on 'em since we were pups. You will soon see that the Keewatin greenstone areas are the foundation to work on, and that they are made up of volcanic lava flows, basalt, andesite, etc. Extending through these greenstone areas and running in a general east by north, west by south direction is found the Temiskaming series, a conglomerate which is easily recognized in the field by its red and black jasper pebbles derived from the iron formation which is usually close by. It is where the porphyry kicks into these volcanics and conglomerates that

the gold values have been found, though not always enough to pay. We usually scout around the contacts of the quartz porphyry and in the porphyry itself if it should happen to be feldspar porphyry.

There is something else that is beginning to look suspicious to us, and that is tourmaline. We have noticed that it seems to have an affinity for high-grade occurring in the volcanics. After you have been in the field a while you will observe there is always a "heart" to these mining camps and that "heart" is well defined by shear zones which extend through the country for miles and are easily followed (general direction a little north of east) and are good prospecting where exposed; but they have a bad habit of running into a swamp or some such low ground. Work along these shear zones and across them at intervals, and when you come to that place where you see silicified schist, well mineralized with fine sulphides and that dark, oily, fractured quartz with black tourmaline,—well, then I would suggest you make camp on that little island and go visiting round with a pick and shovel for a while, and *don't forget to pan*.

You ask me what I think about that Quebec country. Well, the geology is right and it looks like they have another concentration of values. Let's hope they have—it will do us all good. Now about this district, we are work-

The above sketch map will serve to indicate the two belts of Keewatin rocks that stretch westward from the known gold areas and cross the Canadian National Railways near Gogama and Tionaga. Mr. Tom Saville has been at work on the southern belt for several years, with encouraging results. He says there is plenty of room on promising ground in this belt for many more prospectors, and invites them to help him in its exploration and development. —Ed.

ing in. We are convinced that both the Porcupine and Kirkland Lake belts extend and cross the Canadian National to the north of Sudbury. The south or Kirkland Lake-Matachewan-Shining Tree belt crosses just below Gogama at mileage 81, and the Porcupine belt crosses at the Ground Hog river between Foleyet and Tionaga. Lying between the two is another belt which crosses the Grassy River and shows up good at Kam-shawa-pi-ka or "Red Rock." The two southern belts can best be tapped from Gogama, and the Northern or Porcupine belt is best worked from Ka-ka-tush or Ground Hog, which you will see by your map lies a little to the east and south of Foleyet, at a divisional point on the Canadian National.

Now, that's about as far as I can go. I might tell you, seeing that prospectors are few enough, to take good care of yourselves, and every time you come to a rapid and are tempted to run it, land and see if there is a portage. If there is, *pack across*; the Indians must have cut it for some purpose, even if only to keep your grubstake dry. And then on the big lakes, if you have to cross, do it when it's calm—in the early morning or at sunset when the wind usually goes down. And, remember what Drummond said—"You can't get drowned on Lac St. Pierre so long as you stay on the shore." Anyhow, paddle close to the shore, and you won't have so far to swim. Camp on the islands as much as you can—not so much chance of a bush fire starting, to say nothing of being protected from one that someone else has started, and also from the flies—bless their little hearts!

Now, fellows, whether you decide to come up here and work alongside us, or whether you go into Quebec, here's hoping that you catch up with a "concentration" before the snow flies.

Sincerely,  
Hudson's Bay Bill

P. S.—I would like to know how you fellows make out. Write us some time when you feel like it.

### NEW MAP OF LEEDS COUNTY

"Geology and Minerals of the County of Leeds" is the title of Part 6, Vol. 31 (1922) of the Ontario Department of Mines. This report and map by Professor M. B. Baker extends eastward the Frontenac County area mapped on the same scale (a mile to the inch) and published in 1916, and provides the first large-scale map of the area. The geographic base is the excellent contoured map of the Department of Militia and Defence.

The southwestern half of the map sheet is occupied by the pre-Cambrian rocks, principally gneisses and crystalline limestone of the Greenville series intruded by Algonian granite, and is overlaid in places with Potsdam sand stone and basal conglomerate of Cambrian age. Mica, feldspar and granite paving blocks and monumental stone are the economic mineral products of this part. The northeastern portion of Leeds County is underlaid by limestones of Ordovician age, and forms level farming land.

Gradually by means of Professor Baker's mapping this long-neglected part of eastern Ontario is being covered by maps that are not only interesting in the geological sense, but may be useful in aiding a modest mineral development.

During 1922 Canada imported petroleum to a value of \$37,390,000, about two-thirds of it from the United States and the remainder chiefly from Mexico and Peru.

### LETTERS FROM READERS

#### Mr. Nichols' Letter.

We regret that Mr. Nichols' letter last week on page 318 was in one place mangled in the press. At the top of the second column a line was left out, the completed paragraph reading thus: "The definite opinion of those submitting the amendments, in collaboration with a great number of others intended in them, was, and is, that the institute membership should not be restricted to professional men, but should be restricted to men of responsibility, or worth, in, and to, the industry . . . ."

#### The Prospector and Fires

To the Editor,

Canadian Mining Journal.

Sir:

I see by your editorial of April 20th, "The Prospector and Forest Fires," that the lumberman accuses the prospector of starting bush fires, and I note with appreciation that you left very little unsaid in the prospector's defence.

Now, this question of forest fires is one of the most serious in our North Country—serious not only as a great financial loss that affects us all, but serious as a menace to human life. Who, I ask, is more likely to get caught in a bush fire than the man whose work is in the bush, the prospector? What about the lumberman?—you ask. Well, the lumberman about this time is usually safe out of the woods and on the rivers or lakes, driving his winter's cut of logs, or down at the saw-mill, where he has a chance for his life. But the timber cruiser, the surveyor, the geologist, the prospector,—the men who have to camp in the woods when night overtakes them, miles from their canoe or from a lake to give them a chance for their lives—these are the men who know what they are up against. The moment they shoulder their packs and head off into the woods (after submerging their canoe in a creek or sheltered bay, for safety's sake)—you'll agree with me that a bush fire has a *real* meaning to these fellows.

Again, the prospector is often dependent for his daily bread upon that green strip of standing timber—the only kind of timber where he can hope to trap the fisher, marten or beaver that he hunts during the winter to provide his grubstake for next summer's work.

Many more reasons could be advanced to prove that the prospector is *NOT GUILTY* of starting bush fires, but time and space prevent.

In conclusion I will remind the lumberman that the two best fire-rangers he ever had or is likely to have are the two men most vitally interested in the preservation of our forests from fire—the noble Red Man, and Esau, the bona fide prospector.

Gogama, Ont.

Tom Saville.

### MANGANESE-SILVER ORES

A report by the United States Bureau of Mines (serial number 2458) recently issued is entitled "Abstracts from the literature on treatment of manganese-silver ores," by Clevenger and Cornejo. It is a bibliography of 14 pages, compiled by these two researchers in the course of an investigation into the treatment of ores of this character. The references range from 1867 to the present, and the last item is a patented process (1922) by M. F. Fairlie and J. J. Denny, of Cobalt, Ontario, for treating manganiferous ores of the precious metals. The report is available on application to the Bureau of Mines, Washington

# Some of Canada's National Problems

AND THEIR PHYSIOGRAPHIC CAUSE.

BY C. V. CORLESS

(Continued from page 317)

The story revealed is in two chapters. The one is of vast age: the other of extreme youth. The close contact of the two groups of contrasted phenomena is remarkable — more striking indeed, than any poetic antithesis.

## The Ancient Mountain Range

The first chapter tells of a stupendous mountain mass or system, which formed the great primary nucleus or protaxis of North America and which furnished by its erosion much of the material for the more extended balance of the continent. Only the faintest outlines of the remainder of North America had at that remote period been sketched in; and even these outlines were separated from each other, and from the great protaxis, by wide expanses of ocean. Under the incessant action of sun, rain, frost, snow, wind and other geological agencies, acting throughout vast eons of time, probably also with some extraordinary vicissitudes of elevation and depression, this great mountain mass was finally worn down very nearly to what geologists have appropriately called the 'base level of erosion'. This is the briefest possible outline of the chapter of vast age, probably covering many hundreds of millions of years and reaching back into that profound abyss of time before any form of life, either animal or vegetable, had yet appeared on our planet.

## The Glacial Age

The events related in the second chapter, though the last of them ante-dated history by some tens of thousands of years are in comparison very recent. For some cause or causes — whether astronomical, or meteorological or geological, or a combination of these, is not very clear — the earth's climate underwent a great change. The whole earth, and particularly north-eastern America and north-western Europe, became much colder. Throughout hundreds, stretching into thousands of years, snow accumulated in many parts of the world, though our present concern is only with the northern half of our own continent. Finally all the valleys were filled and all the hills or low mountains of the peneplain, that had been left by the previous age-long period of erosion, were covered, to a depth of many thousands of feet. With the steadily increasing depth, and consequent pressure, of snow and ice, slow but irresistible glacial movement began. The accumulation of decayed rock and vegetable mould, the covering of soil but for which land plants and animals, as we know them, could not exist was transported from this area and deposited elsewhere, chiefly to the southward and southwestward. The enormous ice-sheet, equipped on its lower surface with those highly efficient tools of abrasion, viz., loose blocks of rock, stones and grit, moving irresistibly for thousands of years over the solid rock beneath, cut and ground its way ever more deeply into this ancient foundation, rounding, grooving, scratching and polish-

ing the harder formations, gouging more deeply into the softer formations, and gradually producing the glaciated surface practically as we see it to-day. So recent was the final recession of the great ice-cap, and so hard and smooth was the surface it left exposed, that but little erosion has occurred since its retreat. With the several shorter climatic cycles, causing repeated recessions and extensions of the ice-cap, we are not at present concerned.

## Our Heritage from the Glaciers

We are deeply concerned with two of the after-effects of this glaciation. On finally slowly retreating northward to its present restricted areas in Greenland and elsewhere, scattered patches of boulder clay, glacial gravel, sand and rock flour were left indiscriminately in its trail. These scattered patches formed the beginnings of such soil as is found to-day over this great pre-Cambrian area. The second result is perhaps of even greater importance since, among other benefits, it has had the effect in many cases of converting this glacial rubbish into an approach to real soil. The pre-existing well-matured drainage system was completely dis-arranged over the glaciated area. Old stream courses were blocked with glacial rubbish or otherwise changed; many new valleys were partly or completely formed; a completely new surface was left, having little or no relation to the flow of water. In fact, the drainage system of half a continent, the finished topographical product of ages of ordinary erosion, was completely demoralized. Because of the extreme hardness of the very ancient rocks of the pre-Cambrian Shield, millions of years must again elapse before the drainage of this great area becomes once more a mature, orderly system. The muskegs, peat-bogs, lakes, streams, rapids, cascades and waterfalls, to be found anywhere and everywhere, are the visible evidence of this demoralization; as significant to the trained eye of the geologist, as is a disordered room evidence of intrusion to the eye of the keenly observant detective.

Thus are now found together a topography of extreme youth and underlying geological formations of hoary age in this vast area of difficult problems, rigorous climate, scenic enchantment and hidden wealth.

## Drainage

This cursory glimpse of the confused drainage of the pre-Cambrian Shield is about all that can be compressed into one brief address. But before passing on, we must glance at a few additional effects of the recent glaciation of this area which are of great economic importance.

At and near the contact of the extremely hard pre-Cambrian rocks with the softer formations underlying the central continental plain, so intense was glacial scouring and so great was the interference with the drainage when the ice receded, that there are still left, as monuments of this geological epoch, nearly a dozen

of the world's greatest fresh-water seas. All of these are navigable; half of them are already of the greatest importance in the interior commerce of the continent; all are already, or will become an important means of communication between plain and highland. These and the great salt-water sea nearly enclosed by the Shield, Hudson Bay, which is twice as large as the Black Sea, will become more and more important in the transportation system both of this part of Canada and of the central plain contiguous to it. This great sea has only one really large river entering it, the Nelson; a river which has a drainage basin twenty percent larger than that of the St. Lawrence, including its Great Lakes; which drains two-thirds of our Canadian Prairie; and which receives water from the eastern slope of the Rockies.

The dozen great glacial lakes together with St. Lawrence River, nearly encircling the outer rim of the pre-Cambrian Shield, constitute the most remarkable natural interior navigation system in the world. Perhaps equally remarkable is the penetration of Hudson Bay to the very heart of the Shield. But if the glacial demoralization of the Laurentian drainage is remarkable because of its gifts of navigable waters around the rim of the Shield, this glacial action compensated for its destruction of navigable waters in the interior of the Shield by bestowing a second series of gifts which, considering the future needs of the region as well as the limited navigation season due to climate, is of even greater importance. In place of a few large rivers, cut down to easy, probably navigable, gradients, we have in the interior of the Shield almost innumerable small rivers and large streams, scattered almost everywhere, each stream usually having many rapids, cascades and waterfalls. There is scarcely any part of the area not within easy reach of one or more of these water powers. The immense economic value of these in the grinding of pulpwood and making of paper, as well as in the operation of mines and reduction plants, is only recently coming to be adequately appreciated. There are within this area potential waterpowers awaiting development that will yield many millions of horsepower. Most of these are of moderate size, which is a distinct advantage, since this condition favors steady development in easy stages. There are, however, large waterpowers in considerable number, suitable for wide distribution of electric energy and very large enterprises.

#### Resources of the Shield

The previous account of its position, extent, climate, geology, surface and drainage will have failed in its purpose, if it has not prepared your minds for a discussion of the economic resources of the pre-Cambrian Shield. These chiefly will determine its future importance as an abode for man. The immense power available in the very numerous and widely distributed waterfalls will find its chief use in the development, recovery and manufacture, partial or complete, of the material resources of the area. Incidental to this use, this power will afford certain conveniences to those directly or indirectly engaged in, or supported by, the industries carried on in the area. Economic use of power is primary; all other uses are secondary.

#### Forest Resources

Every one knows that most of our lumber, timber and pulpwood are from this area. Plant food being obtained chiefly from the air, forests thrive on remarkably thin soil. Roughly speaking, the southern one-third of this area is clothed with the greatest remaining forest

reserve in North America. Another third of it is sparsely timbered but the economic value of the timber on this part will be but small except as a supplement to other domestic fuel. Already very large pulp and paper industries have been developed in Ontario and Quebec. Considerable inroads into the well-timbered area have been made, partly by cutting but chiefly by forest fires. If cutting is restricted to mature trees and the unused slash is burned, natural re-seeding will occur very quickly. With rigid inspection and enforcement of proper laws for fire protection, our forest industries can easily be made permanent.

The area suitable for forestry and wholly unsuitable for profitable farming is so great that Canadian consumption of forest products can easily be provided for, and a large annual export of lumber and paper continued, without danger of depletion, thus making our forest industries permanent, if conservation of our timber areas is scientifically undertaken. The drainage conditions already discussed make the streams of immense value to these industries. They provide the cheapest means of transporting logs to the mills and furnish abundance of power at low cost for pulp-grinding and paper-making. The problems involved in making these industries permanent are worthy of the closest attention of our Provincial Governments. These problems may be difficult but the difficulties are not insurmountable, if the best brains, supplemented by technical training and broad experience, are employed and given sufficient freedom and backing to solve them. But no time should be lost, since our annual fire loss has been tremendous.

#### Farming Lands

To mention farming is to bring to your minds the much-talked-of "Clay-belt". The fertile soil of this area was deposited as silt on the bed of the temporary glacial Lake Ojibway, during the period when this depression was blocked to the northward by the retreating ice; just as the rich bottom land in Manitoba and eastern Saskatchewan was laid down on the bed of Lake Agassiz; or as the extremely productive border lands of Lake Ontario, comprising the renowned fruit-belt, were enriched while the St. Lawrence outlet of Lake Iroquois was temporarily dammed by the retreating ice-cap. The "Clay-belt", served by the National Transcontinental Line and our Provincial Railway, lying chiefly in Ontario but extending well into Quebec, is said to comprise 16,000,000 acres or 25,000 square miles, equal to more than half the area of Southern Ontario. But Southern Ontario, though important, is relatively quite small, being rather less in extent than two percent of the great pre-Cambrian area we are considering, or about one percent of Canada.

In addition to the "Clay-belt", a considerable number of the larger valleys, large enough for the development of a wholesome community life, and besides these, quite important areas of flat land that once formed part of the beds of lakes temporarily dammed by glacial rubbish but partly drained by the later lowering of their outlets, are suitable for profitable agriculture. But there are already in existence many small settlements of farmers, eking out an existence with no possibility either of economic success or of wholesome social life. Such settlements should never have been allowed to be formed. Only valleys or other soil-covered areas in which proper economic and social conditions can be developed with reasonable effort — areas in which extent, transportation, drainage and soil are suitable for the development of proper living conditions — should be opened to settlement. All the remaining area within the forested zone, should be carefully protected from fire.

so that it may become re-forested by natural re-seeding as the timber is removed. This is clearly a question of great importance demanding detailed land and forest surveys by experienced men of sound judgment; requiring also a clear-cut government policy looking far forward. Our northern land and forest resources are to be of the greatest permanent value to Canadians. The problem is not easily understood by those living in wide continuous areas of excellent farming land, such as you are familiar with in southern Ontario.

The smaller areas suitable for profitable agriculture may perhaps total 25,000 square miles in addition to the larger "Clay belt." But this estimate is, in my opinion, very liberal. A total of 50,000 square miles of land in the entire pre-Cambrian Shield, suitable for profitable farming, is probably all that may safely be counted on. This would be about ten per cent. of the area of that part of the Shield within suitable climatic limits for profitable cultivation or, say, two and one-half per cent. of the entire pre-Cambrian Shield. Relatively small as that is, it is about twenty five per cent. greater than the famous agricultural area of Southern Ontario.

#### Mineral Resources

We thus see that these two basic industries, agriculture and forestry, though based on large resources in the pre-Cambrian area, and of very great present or potential importance, are, because of climatic limitations or recent glaciation, quite restricted in relation to the vast area, more than half of Canada, which we are considering. The one will be limited to about one-third, and the other, probably to about one-fortieth of the total area of the Shield. What, then, may we consider the greatest resource of this area to be? It was natural that hunting should be the first industry developed; natural that the lumberman and farmer should succeed the trapper; equally natural is it, in an area whose underlying rock formations have so recently been exposed by glaciation, that the prospector should now begin to succeed the woodsman. The miner is not limited by climate as is the farmer or lumberman. We have already noted that there is little or no perennial snow in this entire region. Wherever snow and ice do not form a perpetual mantle; and wherever, because of glaciation, geological formation, or ordinary erosion, there is reasonable rock exposure; and particularly, wherever occasional discoveries occur to inspire interest in prospecting; there will men persist in seeking mineral treasures.

But this is merely negative evidence. What positive evidence of mineral wealth in this great area have we? Let us first consider the kind of evidence we may properly look for in such a case as this. Arable land may easily be traversed, measured and tested. Hence, its value may be estimated with reasonable assurance. Forests may be cruised; their water courses may be observed; and reasonable estimates of their value may be calculated on the basis of these observations. But no one can safely predict that a valuable mineral deposit will be found in a given unprospected township; still less safely can one predict what metals will be produced, should a valuable deposit be found; while the height of wild absurdity would be reached, should one have the folly to venture a prediction as to the value of undiscovered deposits that might be recovered from such a closely limited unprospected area. But does this mean that no prediction regarding our undiscovered mineral resources may safely be made?

#### The Basis for an Estimate

Probably some of you are engaged in the business of life insurance. You might not dare to take an unshared

risk of a million dollars on a single life. You might even hesitate to take a thousand medium-sized risks on a thousand lives in one small town of, say, five or ten thousand people. But you would not hesitate for a moment to take these risks, if the individuals insured were widely scattered over twenty counties; still less, if distributed over the whole province; and even less, if over the Dominion. In spite of the unknown liability of death in an individual case, the work of the actuary has made the business of life insurance one of the safest and most certain in its results; far safer is it than that of the single manufacturer.

So is it with the vast area we are considering. With proper precautions as to spreading our risk, very valuable conclusions may be drawn, based on mining results already obtained in known areas and on such knowledge as we have of general geological formations and other conditions of the pre-Cambrian area as a whole. Such general inferences will, of course, be subject to future modification and closer definition, as knowledge obtained by geologizing, prospecting, development, and mining, increases. But it is very important that we make at present the most accurate forecast possible of the probable mineral resources of this great area, inasmuch as this opinion will have much influence in forming our future policy with reference to more than one-half of Canada.

Aside from the fur-trade, exploration and settlement of this area has been approached from the south. Our transcontinental and provincial railways have given access to little more than its southern fringe. Even this fringe has scarcely been scratched by the prospector, except over a few hundred square miles. Hence our direct knowledge of the minerals of the pre-Cambrian area is confined almost exclusively to a small part of this fringe, in which very important discoveries are continually being made and are likely to be made for generations yet.

#### Production of pre-Cambrian in the United States

There are two small projections of this Shield into the United States: one, already mentioned, extends into New York State and forms the Adirondack Mountains; the other passes round the south-western end of Lake Superior, occupying part of Michigan, Wisconsin and Minnesota. These two projections total only 3 or 4 per cent. of the Shield but they have been much more closely examined than the southern fringe in Canada. Both contain enormous reserves of iron ore. In fact, the Lake Superior Iron Ranges are responsible for the pre-eminence of the United States in the iron and steel trade of the world, furnishing, as these ranges have done for years, over 80 percent of the iron ore smelted in that country. Large reserves of rich iron ore remain; and almost incredibly large reserves of lower grade iron ore, estimated at the enormous figure of 70,000 millions (70 billions) of tons, still lie untouched in this area. The technical problems involved in treating the latter are now being attacked on a large scale by a group of the most highly trained and experienced engineers in the United States. But iron-ore is not the only valuable mineral found in large quantities in this Lake Superior area. The world-famous Michigan Copper Mines are in the same area, in the long finger-like peninsula, known as the Keweenaw Peninsula, projecting to the center of Lake Superior. These mines furnished native copper to the Mound Builders; they have been regularly worked for three-quarters of a century; in normal times they were producing annually more than 100,000 tons of the purest copper marketed; and the extent of their remaining ore is not known but is believed to be very great.

Let us next briefly summarize the more important facts of the little we know of the southern fringe in Canada.

### The Iron Formation in Canada

The iron formations at the south-west end of Lake Superior are not confined to the three states mentioned. They continue into Ontario, both around the end of the Lake and across it, the lake being merely a glacial accident. We have numerous iron ranges on our side of the boundary waters, such as Atikokan, Mattawin, Michipicoten, Moose Mountain and others. Our Canadian iron ore deposits have not been sufficiently explored and developed to permit of an accurate estimate. But geologists of the United States Geological Survey, familiar with the deposits similar to these on their side of the boundary, on the basis of geological evidence and such other facts as were available, estimated the iron ore in this formation in Canadian territory, tributary to Lake Superior, at 9,000 million tons, having an iron content of 35 percent or higher. This included neither the Michipicoten nor the Moose Mountain area. Unfortunately the bulk of this ore, as far as exploration has revealed its chemical composition, will require beneficiating before smelting. As already remarked this problem is being seriously attacked in the United States, and a Commission of the Ontario Government is at work on a report on the iron ore problem. The Research Council also is investigating the same problem.

But, though there would be obvious advantages should we find it possible to develop a large iron industry, based on our own ores, on or near Lake Superior, the Lake Superior depression by no means exhausts the possibilities of iron ore discovery in the pre-Cambrian Shield. Belcher Islands in Hudson Bay are known to have an extensive exposure of iron formation, which may afford some foundation for the tentative prediction made by some of the eminent iron-ore geologists of the United States Steel Corporation, regarding the possibilities of the Hudson Bay depression. Probably the greatest advantage Canadians will reap from the extension of the Provincial Railway to Moose Factory and James Bay, will result from rendering the shores of our great northern Mediterranean sea, and the lower courses of rivers entering it, accessible to explorers and prospectors during four or five months of each year. If this works out as expected, it will prove to be the first successful move toward opening up in a large way to steady exploration, our great pre-Cambrian area. The Hudson Bay Railway in Manitoba will have a similar effect, when completed.

### Nickel, Silver and Gold

We may be uncertain as to what value to place on our very large, rather low grade, iron ore deposits. But there is no hesitation in placing a large valuation on the metals already produced by, and still contained in, the nickel, silver and gold mines of Sudbury, Cobalt and Porcupine areas, each of which has become world-famous for its metallic wealth. The mineral riches of these three camps is almost as well known in Toronto as in the North. The numerous copper-nickel ore deposits in the Sudbury area, though the first discovery was made forty years ago and though very large tonnages of ore have been mined during the last thirty-five years, have still in reserve more than 100 million tons of ore. The Cobalt silver area (using the term to include the extensive silver-producing area of which it is the chief center) has already produced close to 12 thousand tons of pure silver, in addition to other valuable metals. Mr. Cyril Knight, Assistant Provincial Geologist, after an extended study of the area, has re-

cently predicted a further long productive life. Porcupine gold area (using the term for convenience in a similar broad sense, to include the roughly parallel gold belts thirty or forty miles apart and extending from Ontario into Quebec) is the youngest of the three great producers but it has progressed with giant strides. Still longer strides appear to be just ahead. I do not need to quote figures. They are in all the papers. The gold production of the Hollinger, Dome, McIntyre and Kirkland Lake mines will be supplemented by that of many others within a few years.

These three, now world-famous groups of mines, Sudbury, Cobalt, Porcupine, have already produced metals of a total gross value of more than five hundred millions of dollars. I am sure you will not be greatly surprised, if I say that, during their total life, the five great groups of mines already found on the southern fringe of the vast pre-Cambrian Shield, viz., Lake Superior Iron, Michigan Copper, Sudbury Nickel, Cobalt Silver, and Porcupine Gold, will produce metals of a gross value, certainly of several, and probably of many, billions of dollars; how many, only a long future will disclose.

Nor should we lose sight of the fact that these five world-famous areas, each of which occupies a first or near-first place among the world's metal producing groups of mines, are not the only well-mineralized areas already known in the southern fringe of the pre-Cambrian. There are numerous others, less in the lime-light, in which patient examination, re-examination, or development is proceeding. Moreover, many less spectacular minerals have been found and worked, some for many years, such as feldspar, talc, graphite, mica, molybdenite and others.

### Projecting into the Future

Now let us consider carefully the significance of these known and proven mineral discoveries. These five fabulously rich mining areas, with numerous other minor discoveries, some of which may develop into very important mines, are all situated in a small part of the pre-Cambrian Shield, the part we happen to have very incompletely examined, merely because it was accessible from settled farming areas, or from the lakes, or because our railways were forced to cross it in order to reach the western plain or the "clay-belt". Next let us reflect on the fact that the remainder of this vast Shield, in so far as it has been revealed to us by a few intrepid explorers, who have penetrated or crossed it in a few places, generally following canoe routes, is known to be broadly similar in glaciation and geological formation. Let us also recall the further fact that, where prospectors have secured a new point of attack as, for instance, near The Pas in Manitoba, made accessible by the Hudson Bay Railway, they have discovered valuable mineral deposits such as Flin Flon, Mandy, and a number of others. Are we not justified in drawing some broad conclusion from these facts? In fact is not some conclusion as to the mineral wealth of the Shield, expressed in general terms, irresistible?

In my Presidential Address to the Canadian Institute of Mining and Metallurgy, a year ago last month, I stated the inference, that appears to me to follow from these facts, in these words: "When Nature transported the soil from this half of Canada to situations climatically more suitable for agriculture, she balanced the loss to future populations by making possible the discovery of inconceivable mineral wealth, which will amply compensate for the greater faith, larger risks, more far-seeing enterprise, and sturdier hardihood, necessary for its discovery and development". Is not this conclusion justifiable? In my opinion, formed gradually during nearly twenty years of residence, and based on careful

observation, experience, and study, in that great region, this is a conservative inference, amply justified by ascertained facts.

### Conclusion

I have referred to this vast pre Cambrian area as the physiographic cause of many of Canada's most difficult national problems. The more you study the relation of this area to the well settled areas of Southern Quebec, Southern Ontario and the Western Prairie; the more you reflect on our national tendency to develop, or even in some cases to over-develop, our comparatively restricted agricultural areas, to the almost total neglect of this greater part of our country; the more you consider the position of the 5,000 miles of railways already built in this territory, their original purpose being chiefly to connect the relatively small and isolated extensions into Canada of the continental plain; the more you come to realize how vast, how compact and how unique is this physical feature, when compared with other parts of Canada east of the Rocky Mountains: the more deeply, I am sure, you will be impressed by the greatness of the problems to which it gives rise; by the reality of its casual relation to them; and by the urgent need of substituting close attention to, and study of, the cause of these problems, for comparative neglect. This group of problems is so vital to our national welfare that we must solve them or risk national disintegration. It is with the hope of conveying to you an outline of this cause, and of awakening a deeper interest in the study of it, that I consented to address you to-day.

We cannot hope to grow into a strong and unified nation by developing our country in isolated patches, which our natural, instinctive love of agriculture has caused us to do. We must make a close study of the intervening area, with a view to its orderly development, not to its exploitation.

It is my opinion that in our mineral wealth, as yet chiefly undiscovered, which we now have such irresistible reason for believing to exist, will be found the best clue to a sound solution for this group of problems. Forest industries, farming, hunting, fishing, production of hydro-electric power, even holiday-making, will all be contributory to the solution. But the key to the solution, the one allurements that will cause men to face the rigors of the north, even beyond the climatic range of profitable agriculture and forestry, will be the hidden mineral wealth, for the discovery of which Nature has by glaciation left the door of her treasure-stocked basement temptingly ajar.

### BENEFIT OF AIR CURRENTS IN MINES

The effect of air currents upon workers in mines has been studied by officers of the United States Bureau of Mines for some years past, and a report, "Physiological Effect of High Temperatures and Humidities with and without Air Movement," by R. R. Sayers and D. Harrington, has now been issued as a bulletin, serial number 2464. The investigations show conclusively that up to a temperature of 98° F. movement of humid mine air reduces considerably the untoward effects that are so noticeable when there is no movement of the air. In still air at a high temperature there is an increase in body temperature and in pulse rate, profuse sweating, and often dizziness and weakness. When the air is kept circulating there is little or no increase in body temperature or pulse rate, sweating is reduced, and after effects are minimized.

### A VISIT TO MR. T. J. BROWN, IN THE NOVA SCOTIA MINES DEPARTMENT.

The other day the writer dropped into the Mines Office, Halifax, where he was met by the new Deputy Minister, Mr. T. J. Brown, with a smile and a warm handshake. While chatting, two questions were sent in from another department to be answered, the exigencies of the moment requiring haste. The Deputy Minister, however, was equal to the occasion and without one moment's delay or hesitation he turned to his own private files and there found the information wanted, although it carried him back over a period of eighty years. It was all done so quietly and yet so quickly and without any assistance from any clerk, that one could not help wondering how much industry it had taken to so gather and record the facts of old-time mining, that it could be found and used in a moment's notice. During most of his life time Mr. Brown has been collecting, compiling and cataloguing information along many lines; and when one looks at the long row of books of Mr. Brown's own making, containing knowledge gathered up in his leisure moments, one can well understand how he was fitting himself for his present position and any other position he might eventually be called upon to fill.

There are some curious facts in these books about things both past and present. They contain the early history of mining in Nova Scotia and many of the original letters that were written in the great battle that raged when the early grants of the coal lands of the Province to a British peer were revoked. Then there is the history of the forming of new mining companies, with the opening up of new collieries in various localities. The events, such as mine fires, floods, or explosions are all recorded. There is also the picture gallery and photos of some of the early mining men who have passed on to finer service. It is most interesting to hear the story and learn of the personal characteristics of such men from the lips of Mr. Brown.

A remarkable letter from the standpoint of a mine manager's interest in his workmen was that written by Richard Brown over fifty years ago. It seems that a Cape Breton miner well known as "Bully MacCormick" had arranged with another miner to have a fight on a certain day at a stated hour. The manager heard of it and wrote a letter to his workmen, beginning with the following very personal touch,—"Friends and neighbours, I entreat you not to go to the brutal exhibition that is to take place on such-an-such a date." He appealed to their humane side, and seemingly not without success, for a foot-note records that "not one man went."

As Mr. Brown has already published one book and has gathered the material for several others, on one of which he is now working, I might be trespassing to further tell of things that I saw and noted.

### HARDENING CONCRETE

Experiments by the United States Bureau of Standards to develop a method of accelerating the hardening of concrete, especially when it is to be used in wet or damp situations, have shown that 4 per cent of calcium chloride added to the mixing water increases the strength of concrete at the age of one day 100 per cent or more. In some cases in two days the strength equalled 75 per cent or more of that normally attained in one month.

The transportation of coal from Sydney, N. S. to Montreal costs about \$1.00 a ton.

# THE MINING DISTRICTS

BY THE JOURNAL'S CORRESPONDENTS.

## NOTES FROM THE NORTH

(Special Correspondence)

**Kirkland Lake** — Six mines are developing one vein system,  $2\frac{1}{4}$  miles in length, at Kirkland Lake, and three of these workings are over 1000 feet in depth. A new company comprising the Elliot-Kirkland and the Macassa on the western end of the main "break" will soon be in operation.

The **Kirkland Lake** or **Beaver Mine**, the western producer in the area, is milling 150 tons daily, the ore coming from various stopes down to the 1000-ft. level. The grade of ore during recent months has been considerably improved, some of the ore on the 800-ft. level being in a dark lamprophyre.

The **Teck-Hughes**, the adjoining mine to the east, which has recently absorbed the Orr property giving a length of 1500 feet on the ore zone, has been producing approximately \$90,000 monthly for several months. The ore averages over \$30.00 per ton and is the highest grade of ore milled in the camp. The shaft is now down 1105 feet, the greatest depth in the area, and the four lower levels are just commencing to be opened up. The 500-ft. level drift has been extended across the Orr property and the 6th. level is also well in on the Orr. A new 3-compartment shaft will probably be sunk and a mill enlargement will undoubtedly be made in the near future while in the meantime the ore reserves are increasing. This would indicate that the property may be on a dividend basis by the end of the year.

The **Lake Shore** 3-compartment shaft is now about 50 feet below the 600-ft. level, the present objective being to sink to and develop the 800-ft. level. The upper levels have been opened up almost the entire length of the property, the ore being treated in a 60-ton mill yielding \$40,000 per month. The mill is being enlarged to handle 300 tons daily. Only recently, a large double-drum electrically driven hoist has been put in operation and a steel shaft house will soon be constructed.

The **Wright-Hargreaves** is also increasing the capacity of its mill, the present output being about 225 tons per day. The cages now run to the 1000-ft. level. The three lower stations at 700, 850 and 1000 feet are in excellent ore; these three levels will now be opened up.

The **Sylvanite**, which is owned by Wright-Hargreaves interests, has developed some rich ore on the 500-ft. level. Drifting and cross-cutting are being done on this level and at the same time the 3-compartment shaft, which is nearing a depth of 600 feet, is being continued to the 800-ft. level. The mine is equipped with a mining plant sufficient to operate in a large way to a depth of 1000 feet or more. Before long this property should be listed among the producers.

The **Kirkland Lake Proprietary**, the easterly producer in the area, has about reached the 800-ft. level.

Extensive lateral operations will be carried on at the two lower levels, namely the 675 and 800-ft., with the hope of putting sufficient ore in sight to keep the 125-ton mill running continuously for some time.

Several other properties are doing extensive operations in the area. The **Continental** is sinking a shaft to a depth of 200 feet on a north-south vein. This property adjoins the Kirkland Lake Proprietary on the east. The **Hunton** is crosscutting on the 375-ft. level. Mining plants are being installed on the **Kirkland-Columbus** and **Highland Kirkland**. Underground operations continue on the **Bidgood**, **Harvey-Kirkland** and **Montreal-Ontario**.

**Larder Lake Area.** — The recently found vein at Pancake Lake on which the Crown Reserve and Associated Goldfields have been developing ore for the past year has been traced by diamond drilling and drifting for a length of more than 3000 feet.

The **Crown Reserve** has crosscut the large No. 2 vein on the 550-ft. level; in about one week hence the No. 1 vein should be encountered. Developments and results to date have been most encouraging, and if drifting on the 550-ft. level gives satisfactory results a mill will be in order.

The **Associated Goldfields** to the west are sinking a 3-compartment shaft from the present 500-ft. level to a depth of 750 feet. Manager T. A. Graves stated at the annual meeting in Toronto on April 26th that the vein on the four levels averaged \$7. to \$10. gold per ton across widths of 5 to 30 feet. If similar values are obtained on the 750-ft. level a mill of about 500 tons daily capacity will be constructed.

The **Anglo-Canadian Explorers**, who have optioned the Emerson claims to the west of the Goldfields, are reported to have encountered continuation of the Crown Reserve graphite vein by diamond drilling. This is the claim on which rich gold-bearing "float" was found and which was diamond-drilled by the Coniagas a few months ago. This syndicate is also obtaining encouraging diamond drilling results on the Walsh-Tucker claims in S. E. Catherine township.

The **Argonaut** mine, 5 miles to the northwest of the Crown Reserve has just completed a 200-ton mill which should commence milling in May. A small tonnage will first be milled and then gradually the tonnage will be increased. Owing to the high copper contents the treatment will be a little out of the ordinary, namely amalgamation, followed by flotation and the tailing cyanided. Important ore-bodies have been developed on the 350-ft. level and at present work is being pushed on the 500-ft. level to encounter the downward extensions of these ore-bodies, which pitch 50 degrees to the northeast.

The **Ossian Mines**, or Hurd-Fishley claims, in Ossian township, have reached a depth of 80 feet with their shaft. The vein across the entire width of the shaft will assay in places \$12.50 gold per ton. The contract calls for 300 feet of drifting on the 100-ft level

**Porcupine.** — On the 400 ft. level of the Vipond a ~~car~~ has been developed, running a little south of east, for a length of 128 feet, over which length the values average \$16.00.

### QUEBEC

**Ville Marie Recording Office** — The minister of Colonization, Mines and Fisheries has issued instructions to open a mining claim recording office at Ville Marie. Mr. Harry Ledden, the recorder at the Bureau of Mines at Quebec, will on May 7th take charge of the new office.

The opening of a recording office at Ville Marie will be welcomed by the prospectors. It means the decentralization of the recording business. Ville Marie being on the most accessible route to the Rouyn camp, the prospectors will be able, on their way out, to attend personally to the registration of their claims and a great deal of unsatisfactory correspondence will thus be eliminated. Recording forms will be more correctly filled in with the aid of the recorder or his assistants. Claims will be at once transferred to the plan, so that an up-to-date map will always be at hand for the benefit of those interested.

At this recording office will be registered mining claims staked in the county of Temiscamingue and a few townships adjoining the Rouyn group. For claims staked elsewhere the recording will still be done at Quebec until such time as it is seen fit to open new recording offices.

**Rouyn Gold Field** — According to P. E. Hopkins, who has recently visited the Rouyn gold prospects, the Powell vein in northwestern Rouyn township which caused the rush of prospectors to the area and which is being developed by the Noranda Mining Co., is 3 to 20 ft. wide for a length of nearly a mile, 500 feet of the vein will average 9 feet in width and channel samples over this section yield favorable assay values. A few grab samples assayed \$6.80 gold per ton. The vein strikes 30 degrees west of north and lies near the contact of a Keewatin greenstone and altered hornblende granite of Algoman (?) age. Portions of the vein are entirely in basalt while other parts are in granite, and values appear to be encouraging in both rocks. The quartz is rose-coloured and stained a rusty brown due to the finely disseminated iron pyrites altering to iron oxide. Forty men are employed under Superintendent Fletcher and Captain Jack Murphy. A considerable amount of trenching is being done and in the near future sinking and drifting will be done. Two small boilers and a 6-drill compressor are already on the property.

A substantial payment falls due in June on the M. Hammill claims which adjoin the Noranda on the north. Much diamond drilling is being done on a vein similar to that of the Noranda.

A proclamation has been issued by the Minister of Lands and Mines, in which all forest land in New Brunswick is proclaimed a protected area. No person may enter any forest land between May 1 and November 1 to camp, fish, picnic or for any other purpose, without first registering with a fire warden, or other authorized person, and obtaining a registration certificate.

### NORTHERN ONTARIO

**Power.** — Three different interests bid for the Quinze power at the recent auction held in the City of Quebec. The bidders were the Montreal Engineering Company (representing the Riordon Company), Nesbitt Thomson & Company, and Mr. Alex. Fasken (representing the Northern Canada Power Company). The power was knocked down to the last at an annual rental of \$80,100 for a term of sixty years. Work on the development of the power will be stated immediately and the company anticipates that by the end of 1924 it will be in a position to deliver 20,000 h.p. A transmission line 120 miles long, with steel towers, will be built to the Porcupine camp and will thus effectually solve the power question, which has retarded the development and expansion of the district for a number of years.

Within the last few days the break-up has occurred and Porcupine mines are now getting sufficient power to operate their mills at capacity. For the first time since the enlarged mill was completed, the McIntyre will be in a position to run it at capacity and will be able to treat about 1000 tons a day, which will add substantially to the production from the district. The Dome, Hollinger and McIntyre together, will treat about 6700 tons a day, while other properties that have been unable to obtain power will be able to go ahead with their plans for development.

It is officially stated that the lease for the development of the Long Sault power on the Abitibi River to the Hollinger has been signed, but as the action between the Power Company and the Hollinger has not yet been settled, it is hardly expected that work will be started until this question is out of the way.

**Kirkland.** — Good progress is being made with the enlargement of the Lake Shore mill and most of the machinery and lumber for the new addition have been ordered and shipped. Steel for the headframe is also in transit. The enlarged plant will have a capacity of 300 tons a day, and it is hoped to have it in operation before the end of the year. During the month of March the company treated 1932 tons and recovered \$40,852, an average of \$21.14 a ton.

The Teck-Huges is proposing to carry on extensive exploration on the 8th, 9th and 10th levels, which will add materially to the ore reserves. Results of development to date on the Orr property have been very satisfactory. The production from the property is being maintained at an average of about \$90,000 a month and the company should soon be in a position to pay off its indebtedness and begin to build up a surplus.

The Sylvanite has again started sinking its shaft below the 500-foot level, and it will be continued a considerable distance before a new level is opened. A considerable amount of drifting has been done and some very favorable indications have been encountered.

The Tonopah Mining Company of Nevada has concluded a working arrangement for three different properties in the Kirkland district, the King-Kirkland, Wood-Kirkland and Moffat-Hall. Shareholders of the King-Kirkland have just ratified a deal under which the Tonopah Company will develop the property and will expend a minimum of \$10,000 every three months. If development is successful and ore to the extent of \$1,000,000 developed, a mill is to be built, the cost of which will be a first charge on the earnings. In this event a company with a capitalization of \$1,000,000 will be formed, of which the Tonopah Company will

get 60% and the King-Kirkland shareholders 40 per cent. The agreement is to remain in force for a period of four years. It is expected that the shaft will be continued to the 1000-foot level. The Wood-Kirkland and Moffat-Hall are to be explored by trenching and diamond-drilling and \$10,000 to be spent on the Moffat-Hall during this year. In the case of the two latter companies the Tonopah will get 70% of the stock of any companies to be formed if developments warrant.

The Bidgood has negotiated a deal for the sale of 1,000,000 shares of treasury stock for \$456,000, the money to be used in the development of the property. The deal was negotiated with J. A. McCausland & Company of Toronto, representing American associates.

The shaft of the Wright-Hargreaves has reached the 1000-foot level and development at this depth is now under way. Arrangements are being made for enlargement of the mill which will bring the capacity up to approximately 400 tons a day.

**Porcupine.** — The Dome financial statement accompanying dividend checks showed that for the year ending March 31st, after allowing \$126,800 for taxes and \$549,488 for depreciation and mine exhaustion, net profits amounting to \$1,877,369 were made. The surplus, which includes a dividend assurance fund of \$1,026,840, stands at \$1,126,694. Net current assets, however, are greatly in excess of this and amount to \$3,077,000. Reserves for plant depreciation and mine exhaustion are carried at \$3,207,243.

During the quarter ending March 31st McIntyre produced \$472,720 and made a profit of \$161,811. The production is very much less than the previous quarter, due entirely to power shortage. For the nine months ending March 31st, there was recovered a total of \$1,666,000 from which a profit of \$689,559 was made, before allowing for depreciation. With sufficient power the company will be able to operate its enlarged mill at capacity for the first time since it was constructed and the earnings and profits of the company should show a very substantial increase.

Nothing new has developed in the Porcupine labor situation, and it is hoped that with plenty of power and work for everybody, this trouble will blow over. The Porcupine camp has suffered greatly from power shortage, and it would be very unfortunate if another setback were given it by a strike of the miners.

**Cobalt.** — The Coniagas expects to have the Beaver mill in operation in June and will be able to treat 150 tons a day. Underground work is being continued and a substantial quantity of good mill rock is being broken. The company has declared a dividend of 2½%, payable May 1st to shareholders of record April 20th.

## NOVA SCOTIA

**Coal Investigations.** — When the Directors of the British Empire Steel Corporation decided to investigate the feasibility of making coke and gas in by-product ovens for the city of Montreal, a new era was opened up to Nova Scotia's coal industry. Shortly afterwards a coal committee was appointed by the Senate in Ottawa to make full inquiry into the coal resources of Canada. The Government of Nova Scotia was the next to follow and now has begun a general stock-taking of its coal supplies in its various coal fields. For this action they were strongly commended by the Mining Society, which recently met in Halifax.

The intention is to ascertain the amount of coal in the coal beds of Nova Scotia; the quality of the different seams with reference to coking; the amount that can be won; the length of time it will take to open up new collieries with the object of doubling the present daily tonnage, and the expenditure necessary to do this work.

This is a big program, but it is being inaugurated by the Provincial Government with vigour and a will to bring it to a successful finish. With a wide knowledge of geological conditions of the Province and the experience gained in practical mining in the different coal fields, it should not be a difficult matter to calculate the coal reserves of the Province. The data gathered within recent years tend to show a much larger quantity than was calculated ten or even five years ago. Some are of the opinion that previous estimates of nine or ten billion tons will be greatly exceeded.

**New Survey of Coal Fields.** — To do this work with precision and despatch, the Government will no doubt engage a capable mining engineer with a knowledge of geological conditions and with large mining experience. He should be familiar with the methods of mining in Nova Scotia and should also know just how long these methods can be carried on with success and what new methods could be introduced and applied to both old and new seams. It is a big job, for a big man, — one who has faith in the mining industry of the Province and who has not yet reached the stage of those who believe that very little more is to be learned of our mineral resources. There are good reasons for thinking that there is yet much coal in certain sections of the Province that will be discovered by a persistent search, and we look forward with faith and hope to a further supplementing of our now known mineral wealth. In the meantime we are getting ready to use the larger "tools of production" illustrated in the "Canadian Mining Journal's" cartoon of a few weeks ago. It is faithful work that is principally required to make the best use of Nova Scotia's coal measures.

The larger coal companies have a fund of new information on which fairly accurate calculation can be based. The British Empire Steel Corporation has spent large sums of money in prospecting their property in Cape Breton, Pictou and Cumberland Counties. Boreholes were put down at different locations to test the depth, thickness and pitch of each seam. Many of the seams proved to be more extensive than was generally supposed. A better knowledge has been gained of the under-sea areas, and better methods of mining by which larger percentages of coal will be won are being evolved with experience.

**Increased Reserve in Pictou.** — The thick seams of the Pictou coal fields have within recent years been proved to contain a much greater amount of coal than was at first calculated. To the large number of seams known for many years a number of others were added about four years ago, all having been found lying at workable depths, one above the other. There are still those who believe that there is much yet to be learned about the coal beds of Pictou County. Here probably more than in any other part of the Province will be witnessed the greatest development of the coal industry in coming years.

That the Springhill coal fields have surprises in store in the way of extensive seams of a fine quality, is

the common belief of mining men who have knowledge of the district. There are few pessimists on the coal question in Nova Scotia and we are inclined to think that when a general survey has been taken, the prospect will be pleasing.

**Analyst to Examine all Coal.** — The quality of the coal is to be determined by an expert analyst, who will test samples from every seam so far determined in the Province. This will form a basis for determining the amount of coal that can be used for coking. There is much to be done along this line, for although in a rough way much knowledge has been gained of most of the seams now being worked, the data are not accurate and the work of gathering information will only be done rightly when it becomes the duty of some person specially appointed for the purpose. For too long the Government of Nova Scotia has been content to receive its knowledge at second hand from the different coal companies, and if, as we are informed, it is about to appoint capable, educated and well-trained men to gather and compile facts about its own mineral resources, it will have taken a long step forward and will be in a position to point with some degree of pride and assurance to the resources the province really does possess.

**Increased Production to be Gauged.** — While this is going on, the coal operators are to be approached to find out what it will cost and the time it will take to open up and develop a sufficient number of new collieries to double the present output. The British Empire Steel Corporation mines eighty-five percent of the present output and is, therefore, in a better position than any other company to give the needed information. It is highly organized and can tell within a few days and a few dollars the money and time necessary to open up the needed collieries. The only uncertain factor is that of labour, and this too may some day soon come down to a spirit of sweet reasonableness. At present it is the unknown quantity and as such it will have to be treated. All other factors being well known, the Government of Nova Scotia will in the future be in a much better position to point to its coal fields and say just how long they will last, and what quantity can be depended upon each year.

**Gold Mining.** — The gold mining industry of Nova Scotia is to receive more attention from now on, and while the same critical examination into the extent of the gold-bearing ores may not be made just now, there will, however, be sufficient direction and supervision given to ensure more intelligent and modern methods in mining, and more profitable processes in gold extraction. Indeed, it would not be any surprise to see an experienced gold miner placed in the field again to advise and direct all effort along practical and economic lines. In this way prospectors and owners of mineral property would from the very beginning be spared much useless expenditure of money and energy and when difficulties did arise in their operations, they would have the advice of one who knew how to overcome them. For prospecting in difficult and almost inaccessible places a light boring equipment is to be supplied. All information about land leases, etc., and all ore samples will receive the prompt attention of the Mines Department. Clearly the department is out to do the most it can for the gold mining industry of the Province.

## ALBERTA

**Coleman Team Wins Cup** — First Aid Team No. 1 of the International Coal and Coke Co., Ltd., of Coleman, has added to its laurels by winning recently the Montizambert Cup from a field of 58 entries from coast to coast. The runners-up were No. 1 Team of the Grand Trunk Railway Shops Stratford, Ontario with No. 1 Team, City Police, Winnipeg third and a team from the Consolidated Mining and Smelting Co. of Trail fourth.

At a public meeting in the opera house at Coleman on April 18th the cup was presented to the winning team by Professor Ottewell, Hon. Sec-Treas. for Alberta of the St. John Ambulance Association. The team comprised Messrs. W. White (captain), D. Roberts, R.M. Greenhalgh, J. D'Andrea and R. Morgan. After the presentation the team received a substantial cheque from the International Coal and Coke Company. Mr. O. E. S. Whiteside, general manager, and Mr. D. Davies, mine manager of the company have taken an active interest in the work of their First Aid teams, the latter being secretary of the St. John Ambulance Association in Coleman.

This is the second important trophy this team has won lately. The Coderre cup, open to competition by mining teams throughout Canada, was won by them for 1922. They have also won a number of other prizes during recent years, including those offered by the Rocky Mountain branch of the Canadian Institute of Mining and Metallurgy. This team is therefore undoubtedly the champion all-round First Aid team of Canada.

## BRITISH COLUMBIA

**Trail Ore Receipts.** — Ore receipts at the Trail smelter, Consolidated Mining & Smelting Co., for the second week of April totalled 10,020 tons, made up as follows:

| Company                                                 | Tons |

10,020

**Dredging Proposed in Revelstoke District.** — The installation of a gold dredge on Gold Stream, near its confluence with French Creek in the Big Bend district of which the city of Revelstoke is the centre, is proposed by the Cal-Canadian Gold Dredging Company. H. E. Moore of San Francisco has secured leases of the ground and is reported to have obtained the financial backing required to proceed with the enterprise.

**Smithers.** — A quarter of a million dollars, it is reported, has been advanced by Messrs. Trites and Wood, of the Premier Mine, for the installation of a concentrator and to provide for further development on the

Babine Bonanza, which James Cronin has been working on for several years. Mr. Cronin was the operator who brought the St. Eugene Mine to the point where it attracted the Canadian Pacific Ry. Co. and subsequently became a large producer. He believes that his northern property will prove to be even a better paying proposition.

**Ainsworth.** — The Florence Mine has been turned over to a syndicate, composed chiefly of Detroit business men, for a consideration of \$1,250,000 and an agreement to spend \$450,000 on development. The terms of the undertaking, which already have been outlined in these pages, have been confirmed. Generally speaking it is a re-organization having as its object the bringing in of new capital. The result, it is said, will be the securing immediately of necessary equipment, development underground on a larger and more systematic scale than heretofore, and generally the placing of the mine on a better basis in point of operation and of production.

**Mining Boom Pending.** — R. H. Kergin, M.P.P., the representative in the British Columbia Legislature of the largest mining district in the West, including as it does both the Portland Canal and the Atlin sections, has returned after touring the cities of eastern Canada and the United States. He says: "The Premier Mine is much more talked about in the East than it is here and there is a great deal of American capital being sent into the country. We are on the eve of a real boom in mining although the people of British Columbia apparently do not recognize this to be a fact."

**"Another Big Mine."** — Dr. George Hanson, of the Canadian Geological Survey, recently addressed the Vancouver Island Prospectors' Association on the geology of the Salmon River District, Portland Canal. He said that the B. C. Silver, next to the Premier, looked like another big mine.

**Mr. Mathewson, for B. C.** — Mr. E. P. Mathewson, formerly of the Anaconda Copper Company, has accepted an appointment as consulting engineer on the staff of the Granby Consolidated Mining and Smelting Company.

**Dual Control in Railway Belts.** — Along the line of the Canadian Pacific Railway in British Columbia there is a strip of land, twenty miles in width on either side known as the "Railway Belt", and the minerals within this area belong to the Dominion Government as to the base metals and the Provincial Government as to the precious metals. In 1890 an order-in-council was passed at Ottawa giving the administration of the base metals to British Columbia and the mineral lands of the "Belt" automatically came under the terms of the "Mineral Act" of the Province. It was thought that the vexatious dual control condition had been eliminated, and it was for a time. A time arrived, however, when the Province applied without satisfaction for the purchase on behalf of a mineral claim holder within the "Belt" of the surface of the land within his claims. Title to the surface under the Agreement would carry the base metals and the Province then would be in a position to convey both precious and base metals under the "Mineral Act." But the Dominion, in the interim, had disposed of the land involved. Its grant carries the minerals and the Province was unable to satisfy the prospector, who had staked in good faith and had fully complied

with the provisions of the provincial law. This is typical of more than one experience. Further complications were caused by the creation of Forest and Park Reserves by the Dominion within the Railway Belt. Withholding of the surface from alienation meant the barring of the particular areas affected to prospectors and to mineral development. Thus a situation has been growing up which the Province considers is seriously hampering the advance of the mining industry. Hon. Wm. Sloan, Minister of Mines, was in Ottawa recently and the issue briefly outlined is one of the matters he discussed with Hon. Charles Stewart, Federal Minister of Mines, and other members of the federal government.

Other blocks exist in British Columbia in regard to which there is similar conflict of authority as between the Province and Dominion. There is the Peace River Block in the northeastern corner of the Province. The royal or precious metals are vested in the Crown in the right of the Province of British Columbia, as is always the case, but the vulgar metals are controlled federally. There is nothing more stultifying than dual ownership when applied to natural resources for the development of which capital is essential. It has proven so in the E. & N. Ry. Belt, Vancouver Island, where the Province and the railway company share authority as to the minerals and at the present time the problem of having this complex situation adjusted and the British Columbia Department of Mines placed in full charge is being amicably worked out by the two principals affected. Mr. Sloan proposes taking up with Ottawa the mineral administration of the Dominion Peace River Lands. He recognizes that if the administration of the minerals within the Island and the Mainland Railway Belts, as well as those within the Peace River Block, can be brought under the Province without reservation it will be an achievement of the highest importance to the mining industry of British Columbia.

## PRODUCTION OF BAUXITE IN 1922

The production of bauxite in the United States in 1922 was 309,600 long tons, valued at \$1,935,800, according to the Geological Survey. These figures show an increase of more than 100 per cent in quantity and of more than \$1,000,000 in value over those for 1921. The Arkansas field produced 266,799 tons, more than double the output in 1921, but still less than half of its yearly maximum. The eastern fields, in Alabama, Georgia, and Tennessee, produced 42,810 tons, nearly four times as much as in 1921 and about the maximum output from those fields. Georgia leads, with an output of 30,417 tons.

Bauxite produced and consumed in the United States, 1921-22, in long tons.

## RACIAL ORIGINS OF CANADIANS

People of British origin constituted 50.40 per cent. of Canada's population in 1921, according to a statement issued by the Dominion Bureau of Statistics. In 1921 English made up 28.26 per cent. of the population; Irish 13.33 per cent.; Scotch, 13.36 per cent.; French, 27.91 per cent.; and all other European races 8.59, i.e. Asiatics made less than 1 per cent. of the population in 1921. More than 81 per cent. of the population in 1921 were of British and French racial stocks.

### PURCHASE OF GOLD ORES

The attention of prospectors and others is drawn to the provision in the Mining Act of Ontario authorizing the Department of Mines to purchase parcels of gold ore taken out by prospectors and others in developing or working mining claims. Arrangements have been made by which such parcels of gold ore, whether large or small, will be accepted by the Temiskaming Testing Laboratories at Cobalt, and paid for according to the schedule provided for the purpose. The Laboratories are operated under the auspices of the Department of Mines.

This offers a first class opportunity for testing the value of ores on a large scale, and also of turning ore of good quality into money for carrying on further development work. By special arrangements, on less than carload lots, freight rates on the T. & N. O. Railway are reduced 50 per cent.

The Laboratories are also equipped for working out the best methods of treatment for gold or silver ores of a refractory or unusual character.

Full information as to treatment charges, schedule of payments, etc., can be obtained from the undersigned, or from A. A. Cole, Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

THOS. W. GIBSON,  
Deputy Minister of Mines.

# PROVINCE OF QUEBEC

## MINES BRANCH

Department of Colonization, Mines and Fisheries

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, etc.

MINISTER OF COLONIZATION, MINES AND FISHERIES, QUEBEC

**MINER'S CERTIFICATES.** First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is \$10 and is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

**WORKING CONDITIONS.** During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

**SIX MONTHS AFTER STAKING.** At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

**MINING LICENSE.** The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year, and a fee of \$10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days' labour on each forty acres.

**MINING CONCESSION.** Notwithstanding the above, a mining concession may be acquired at any time at the rate of \$5 an acre for SUPERIOR METALS, and \$3 an acre for INFERIOR MINERALS.

The attention of prospectors is especially called to the territory in the North-Western part of the Province of Quebec north of the height of land, where important mineralized belts are known to exist.

**PROVINCIAL LABORATORY.** Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, Montreal, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

**HONORABLE J. E. PERRAULT,**

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

## The Mineral Province of Western Canada

Has produced Minerals valued as follows Placer Gold, \$76,542,203; Lode Gold, \$109,647,661; Silver, \$52,814,266; Lead, \$51,810,891; Copper, \$170,723,242; Zinc, \$24,625,839; Coal and Coke, \$238,289,565; Building Stone, Brick Cement, etc., \$36,605,942; Miscellaneous Minerals, \$1,358,839; Making its mineral production to the end of 1922 show an

**Aggregate Value of \$734,259,619**

The substantial progress of the Mining Industry of this Province is strikingly exhibited in the following figures, which show the value of production for successive five-year periods: For all years to 1895, inclusive \$94,547,241; for five years, 1896-1900, \$57,605,967; for five years, 1901-1905, \$96,509,968; for five years, 1906-1910, \$125,534,474; for five years, 1911-1915, \$142,072,603; for 5 years 1915-1920 \$189,922,725; 1921, \$28,066,641; for the year 1922, \$35,158,843.

**Production During last ten years, \$339,280,940**

Lode-mining has only been in progress for about twenty-five years, and not 20 per cent. of the Province has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those of any other Province in the Dominion, or any Colony in the British Empire.

Mineral locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown's Grants.

Full information, together with Mining Reports and Maps, may be obtained gratis by addressing.

## 8928-Hour's of Continuous Grinding -- Without a Moment's Shutdown

Just think — One of the Hardinge Mills at Nevada Con. ran for over a year without stopping for any cause whatsoever.

Did you ever figure what it costs to shut a mill down even for an hour? Figure it out for yourself and you will be surprised.

Example:

If your mill is grinding an \$10.00 gold ore at the rate of 10 tons per hour, and is shut down for an hour, \$100.00 are lost beyond recovery.

The Hardinge Mill is simple. It is due to this simplicity that it keeps running right along, day in and day out, for months at a time so smoothly that once installed it is all but forgotten and figures covering the cost of shutdowns are too small to bother with.

- Summary Report of the Mines Branch, 1920.  
The Mines Branch maintains the following laboratories in which investigations are made with a view to assisting in the development of the general mining industry of Canada:—
- Fuel Testing Laboratory.**—Testing value of Canadian fuels for steam raising and production of power gas; analyses, and other chemical and physical examinations of solid, liquid and gaseous fuels are also made.
- Ore-Dressing Laboratory.**—Testing of Canadian ores and minerals, to ascertain most economical methods of treatment.
- Chemical Laboratory.**—Analysing and assaying of all mineral substances and their manufactured products. Copies of schedules of fees, which are slightly in excess of those charged by private practitioners, may be had on application.
- Ceramic Laboratory.**—Equipment is such that complete physical tests on clays and shales of the Dominion can be made, to determine their value from an economic standpoint.
- Structural Materials Laboratory.**—Experimental work on sands, cements and limes is also undertaken.
- Applications for reports and particulars relative to having investigations made in the several laboratories should be addressed to The Director, Mines Branch, Department of Mines, Ottawa.
- Summary Report. The annual Summary Report of the Geological Survey is now printed in parts. Applicants should, therefore, state what particular geologist report is required, or what subject they are interested in.
- Memoir 108. The Mackenzie River Basin, by Charles Camsell and Wyatt Malcolm.

# Ontario's

# Minerals

PROVINCE OF ONTARIO

DEPARTMENT OF MINES

HON H. MILLS, Minister of Mines

## Mineral Areas.

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favorable for the occurrence of minerals, 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver mines of Cobalt occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

## Economic Minerals.

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario:—actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluor-spar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, portland cement, brick and tile, meet every demand.

## Mineral Production.

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1921 to be worth \$48,128,387, of which the metallic production was \$27,574,202.

The following figures show the rapid growth of Ontario's mineral industry by five-year periods since 1891:

| Year.          | Value.      | Year.          | Value.       |
|----------------|-------------|----------------|--------------|
| 1891 . . . . . | \$4,705,672 | 1906 . . . . . | \$22,388,383 |
| 1896 . . . . . | 5,235,003   | 1911 . . . . . | 41,976,797   |
| 1901 . . . . . | 11,881,086  | 1916 . . . . . | 65,303,822   |

## Dividends.

Dividends and bonuses paid to the end of 1921 amounted to \$23,140,734 for gold mining companies, and \$84,388,185 for silver mining companies or a total of \$107,528,919.

## Mining Regulations.

A miner's license costs \$5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of \$2.50 or \$3.00 per acre, depending on location in unsurveyed or surveyed territory.

## Assay Office.

The Provincial Assay Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

## Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

# Serving Canada's Mining Industry

It is many years since The Imperial Bank of Canada, recognizing the importance of the Canadian mining industry and realizing the need of banking facilities for those engaged in its development, first opened a branch in Northern Ontario.

Since then the Imperial Bank's service has gradually extended until the mining interests in the rich area between North Bay and Hearst are now linked up by a complete chain of 12 branches.

This Bank's service to the mining industry is not confined to Northern Ontario alone. In all the mining areas throughout Canada the "Imperial" is rendering a valuable and complete financial service.

### HOLMAN "C.H.2" Cradle Hammer Drill BREAKS THE WORLD'S STOPING RECORD AT THE VAN RYN DEEP GOLD MINE

#### THESE ARE THE FACTS

This Record was achieved in Stope 3, East 9, Eastern Shaft, Van Ryn Deep Gold Mine.

September 2nd to October 1st, 1921.

Working Shifts 26.

Total Fathoms Broken 248

Stope width 69 ins.

Type of Drill — "Holman" Cradle Hammer (C.H.2)

Number of Machines 3

Machine Shifts 78.

Fathoms per Machine Shift 3.18

Contractor: B. T. Lellyett

Equipped with "4810" Air Hose

Manufactured by

## THE FREIGHT RATE ON COAL

Sir Henry Thornton has announced that the Canadian National Railways will give an average rate of \$9 a ton on coal from Alberta to points in Ontario. This is a reduction of \$3.70 a ton from the rates heretofore in force. Mr. Howard Stutchbury, representative of the Alberta government on the question of western coal for Ontario, states that only with a rate of \$6.00 a ton can Alberta coal compete in Toronto with that from the United States.

We would judge that Sir Henry Thornton's announcement marks the first stage of a "dicker". He has specified wisely that no freight rate on coal from Alberta to Ontario shall entail an operating loss for the railway under his control. With this there can be no serious disagreement. The final point will be to determine what the operating cost is. This is still to an appreciable extent a matter of conjecture. Sir Henry Thornton is "playing safe" by putting the rate at the comparatively high figure of \$9.00—a rate that nevertheless seems very reasonable under the known circumstances.

In evidence before the Senate Committee on Fuel last week, Mr. M. J. Butler repeated the calculations he had made formerly, which were quoted at the annual meeting of the Canadian Institute of Mining and Metallurgy in Montreal last March. He says that, with cars and engines constructed for the purpose, train-loads of coal carrying 5000 tons can be hauled profitably over our Transcontinental line, with its maximum grade of four tenths of one per cent, for \$3.50 a ton from the mines to Cochrane, a distance of 1,750 miles. This corresponds with \$4.40 a ton to Toronto; but the grades from Cochrane to Toronto are not so favourable, and an allowance must be made for the added expense involved. Considering that Sir Henry Thornton's figure is based upon existing rolling-stock and present terminal facilities, obviously far below the standard of efficiency Mr. Butler specifies, the difference between the two rates is not hard to understand.

Besides the Canadian public, which has the largest interest at stake in this problem, there are three groups concerned — certain of the Alberta mine operators, the Canadian National Railways, and wholesale coal dealers in Ontario. The most favourable result to the public will be attained only if the conflicting interests of these groups are modified in accordance with a conclusion that will benefit all in the long run. The Canadian National Railways are the first to offer a concession, which we would judge may be substantially increased

if trial shipments show it is warranted, and which is most certainly capable of betterment if special equipment is provided. As these conditions for a still lower freight rate are contingent, the first upon trial shipments and the second upon steady shipment of coal from Alberta to Ontario, we would judge it to be well worth while for the miners of Alberta and the coal dealers of Ontario to accept Sir Henry Thornton's offer, with such additional concessions as he may be able to provide as a means of testing this possible solution of Canada's fuel problem.

## PROFESSIONAL BUSINESS PROPHETS

The number of vocations that arrogate to themselves the title of "profession" is continually being added to. The latest is probably that of the business prophet. Indeed, at no previous period in the world's history has anything like a tithe existed of the number of people who deem themselves fully qualified, with almost pontifical authority, to forecast business conditions.

This forecasting of future conditions, by means of diagrams or charts of the past, seems not only to have a strong fascination — and also, one imagines, a very profitable one — for those who practise it, but it also hits the taste of the general public. Few things, indeed, are more surprising than the way in which business men, big and small alike, seem ready to pin their faith to predictions based on these diagrams and charts. And this in spite of the fact that the predictions in question have an awkward way of being falsified, more often than they are ratified, by events.

"The worst of great thinkers," once said John Bright, "is that they generally think wrong." The forecaster of business conditions — the diagrammist and chartist — has this, at least, in common with the "great thinkers" of whom Bright spoke — he is generally wrong. Not invariably, of course. Not everyone who essays to forecast conditions in the matter of a horse race loses his money. People have been known, ere now, to break the bank at Monte Carlo. And just as the "plunger" who backs a "certainty", or the gambler with an "infallible system" sometimes guesses right, so, too, does the business "tipster."

But, it may be said, the business forecaster has his data to go on — his records of financial, commercial and industrial conditions in the past. Well, so has the race-course punter his "racing form"; and the "system" of the sportsman who essays to "break the bank" is not infrequently based on some more or less murky

lore regarding the ratio of the number of ways in which a particular event may occur to the number of ways in which it may not occur.

The truth of it is that the business forecaster with his diagrams and charts and his learned talk about "cycles" and all the rest of his professional paraphernalia is up against one supreme and, to our thinking, insurmountable difficulty. In predicting that a period of prosperity will be followed by a period of depression he is on sure ground. But, when he attempts to measure with any approximate accuracy the length of any given period of business prosperity or business depression, he encounters the difficulty of which we are thinking. Charts of these business conditions in the past would be helpful enough as a guide to the future if only those who put them forward as such could ensure that the determining factors to confront us in any given future period would be precisely the same as those encountered at a given period in the past. That, of course, they cannot do. And if the causes—that is to say, the determining factors—differ, the effect cannot be predicated to be the same.

This is not to say that existent conditions should not be analyzed or that attention should not be paid to symptoms. But the theory of periodicity in the alterations between prosperous times and times of depression is, and must necessarily be, always liable to be upset by particular forces at work at a particular time. A chart of the past, before the war that was to end all war, for example, can be of little use as a guide to the future to the world in its inflammable state today. For our part we believe in letting the forecaster's charts and diagrams alone, and devoting the time and energy which are required for their study to the work that needs doing now, leaving the future with its "cycles" to take care of itself.

#### USEFUL EXCURSIONS FOR M. P'S.

To the generality of Canadians the mineral industry of their country is little but a phrase, illustrated principally by flaunting advertisements in the daily papers soliciting subscriptions to doubtful mining stocks. Our representatives in Parliament are, with few exceptions, almost as ignorant of the facts of this great basic industry.

There was illustrated last week a potent means of informing the members of Parliament about our natural resources, and through them, their constituents. Senator Smeaton White of Montreal entertained a party of senators and members of the House of Commons in Shawinigan, Grand'Mere and Three Rivers, where they inspected the water power development and the industrial plants based upon the hydro-electric power. Most of the members of the party were from the West. All were informed at first hand of the facts about one of the East's most promising industrial centres.

This means of spreading abroad throughout the land authentic information about our resources might well be applied to the mining industry. Ottawa has within convenient range the asbestos district of Quebec, the Sudbury nickel deposits, the silver mines of Cobalt, and the gold mines of Porcupine and Kirkland Lake. The mining, milling, smelting and refining operations of all these camps can be made comprehensible to non-technical men. Their importance to Canada can best be impressed by a view of the industries they have created.

There are in Ottawa public representatives interested in the mineral industry in the same way that Senator White is interested in the industrial activities of the St. Maurice valley. Would it not be worth their while to co-operate with authorities in the mining camps with a view to arranging similar excursions of parliamentary representatives?

#### THE BRITISH EMPIRE EXHIBITION

Plans are maturing rapidly for Canada's participation in the great British Empire Exhibition to be held in London next year during the six months from April to October. Our national government has been very slow in deciding on Canada's share in this huge enterprise; but we can now be confident that out of their mature deliberation will proceed a plan of operations worthy of the principal British Dominion.

Canada's national exhibit will be housed in a building with 124,500 square feet of floor space, 415 feet long and 300 feet wide, and will be financed and controlled exclusively by the Federal Government. Our two great railway systems will have each a separate building for their own purposes. The Canadian building will exhibit the resources and products of each of the nine provinces and two territories.

Many are the problems of Empire. The present Exhibition is designed expressly for the purpose of promoting trade within our empire. The bonds that have knit into a political unit the scattered lands that call themselves British have been to a great extent engendered and strengthened by trade and commerce with the mother land. Of recent years these bonds have become loosened, with grave danger to us all. Many students of affairs have pointed out the present unrivalled opportunities for inter-imperial intercourse to the common benefit of all. The British Empire Exhibition is a practical attempt, on a vast scale, to put these opportunities to the test.

Seventy-two years ago the first of the great Empire exhibitions, that of 1851, was held in London, and the famous Crystal Palace still reminds the Londoner of its success. The "Exhibition of 1851" scholarships for students in science, awarded annually in all the British Dominions, were endowed by surplus funds from the exhibition and are a permanent and striking memorial of its financial success. We cannot hope for a direct monetary return from the present imperial un-

dertaking; but the final results from the intercourse of millions of Britons from all quarters of the globe in Wembley Park during the summer of 1924 are sure to measure up to the opportunity the Exhibition is designed to meet.

### WELCOME, GRADUATES OF 1923!

During this month the 1923 graduates in mining and metallurgy of our various universities will launch forth into their professional careers as engineers. The numbers this year will be large, on account of the numbers that were prevented from commencing their courses of study during the war years and entered the universities in 1919. Fortunately our mining and metallurgical industries are now so active that they are quite capable of absorbing these recruits and making good use of them.

It is characteristic of the Canadian student of engineering in our universities to employ himself seriously on a "job" connected with his future professional work during his summer vacations. Many, indeed, come to the universities only after they have found from practical experience that they can improve their professional prospects by further intra-mural study. Hence the task that devolves upon the older engineer, established in his practise, of welcoming and assisting his young confrère is made more pleasant and easier. There are few mines or mills in Canada today where the young graduate does not receive a cordial welcome, and in most the manager will even stretch a point to provide him with employment and give him a start. This is in marked contrast to the prevalent spirit twenty-five years ago, when the young college graduate acquired a vernacular and a good stock of cuss-words and chewed tobacco even to the point of sickness in an attempt to conceal the fact of his scholastic training.

The "Canadian Mining Journal" welcomes the addition to the fraternity of the 1923 graduates in mining and metallurgy, and hopes that the success of their budding professional careers will match the sure progress of Canada's mineral industry.

The gold vein on the Powell claim of the Noranda Mining Company in Rouyn township, Quebec, was well described in the "Northern Miner" recently by Mr. P. E. Hopkins, of the Department of Mines, Toronto, who visited the property just before the break-up. Mr. Hopkins, who is familiar with all the active gold properties in Ontario, thinks very highly of the Noranda vein after his inspection. "Noranda" is, by the way, a contraction for "Northern Canada", — not the name of somebody's best girl!

More than one attempt is under way to utilize the bituminous material contained in the vast deposits of "tar sands" on the Athabaska River. A serviceable asphalt pavement in Edmonton attests the utility of the sand in aiding the movement for good roads; but its

commercial use is feasible only if the valuable bituminous constituents are extracted for shipment.

The report that Mr. W. P. Hinton is to erect at Fort McMurray a small plant for extracting this bituminous material and producing from it tar, oils and gasoline may be premature, but it is nevertheless interesting as indicating the present active interest in the problem.

The season has commenced once more. We do not refer to the season for prospecting, but to the fishing season — the open season for "suckers." Already the public are regaled with suggestions of "another Hollinger", coupled with an invitation to buy stock in the prodigy. It is "hardly believable so much gold exists in any one area", it is stated in half-inch, black-face type, while in small type, in a previous advertisement it is stated that the estimated ore disclosed is 36,857 tons, of an average value of \$9.77. Luckily the Sale of Securities Act is now safely through the Ontario Legislature, and we may hope for a perpetual close season for "come on" advertisements for mining stock in that province at least.

An article by Mr. Jules Descamps in the "Revue de Paris" describes the way in which the German Mark is being replaced by various methods of calculating values. Industrialists, for instance, find it advantageous to pay wages to some extent at least in kind, and leases and property change hands in prices calculated in goods. A quintal of coal is regarded as a currency unit in Hanover and Westphalia, whilst Oldenburg and Mecklenburg-Schwerin issue bonds reckoned in barley. He considers that these diversions from the use of the Mark as money are but temporary expedients on the way to the adoption of a new gold standard, and that during the period of transition wholesale bankruptcies and other disastrous economic consequences may arise.

### LAKE FORTUNE PROPERTY OPTIONED

The property of the Lake Fortune Mining Company, Limited, in Boischatel township, northwestern Quebec, is now held under option by Messrs. A. A. Mackay and W. P. Alderson of Montreal. The terms of the agreement are coöperative, involving an option on the stock of the present company, and Messrs. Mackay and Alderson are allowed until July 1st. to examine the property, free of any obligation, before exercising their option. This examination will be commenced immediately travel is possible on Lake Opasatika.

In his recent article on the Quebec gold field, Dr. H. C. Cooke makes some interesting references to the property of the Lake Fortune Mining Company. "The Lake Fortune deposit occurs in a belt of highly schistose basalt that runs slightly north of east and has clearly been formed by faulting . . . . . Porphyry dikes are found on the property of the Lake Fortune Mining Company, and mineralization is most intense close to the dikes, dying away with increasing distance from them."

## Playing the Great Woods Game - II

### THE FIND

BY TOM SAVILLE

Toronto University,  
November 1st,—

Hudson's Bay Bill,  
Muskeg-Gogama,  
Ontario

Hello Bill! You will be glad to hear that we made good in our prospecting. We had a great summer, and we learned lots of things, camping out in the woods, that we might have lived and died in the city and never got wise to.

But about our prospecting; we acted on your suggestion and dropped off at Kirkland Lake on our way up to Cochrane, where we planned to take the Canadian National for La Salle and go into Quebec. We were very agreeably surprised at the courtesy and kindness shown us at the mines when they learned we were prospectors. They seemed to take a special interest in us, and pointed out the different rock formation and the general characteristics of the camp. We got a good look at your friend the Timiskaming conglomerate, and took particular note of it, especially the pebbles of red and black jasper. We also took particular notice of the feldspar porphyry, the syenite and those lamprophyre dikes, and altogether we came away from Kirkland Lake very much encouraged by the mining men and keen to dig up another camp like it.

We took the train again, intending to go straight through to Cochrane, but were prevailed upon by a friend at the Hollinger Mine to run into Porcupine and give the camp the once over. There we were dined and wine and fussed over and shown through the camp and we were made to feel that a prospector is considered "some fellow" in the North. We were shown around the contacts of those two big canoe-shaped intrusions of quartz porphyry into the basalt, with Hollinger Mine on one side and McIntyre on the other. Then we were taken over to the Dome and again saw where the porphyry had acted kindly by kicking into the Timiskaming and depositing a few dimes and nickels.

We came out of Porcupine with the feeling that we were especially anointed and appointed to go forth into the wilderness and pull the moss off another Dome or Hollinger, and for that reason instead of following the crowd into Rouyn district Quebec, we had the National train stop and put us off where we figured the Rouyn belt crossed the railway, and worked in from there.

Well, we might have been mistaken for the Babes in the Woods for the first few days,—but only for the first six, for on the seventh day, my pardner and I could wash a shirt, pound up and pan, or bake a bannock like any other old timer.

We worked along the belt, moving camp about once a week. But the summer was well on before we began to get action, although several times we had false alarms rung in on us. One time we ran into an ideal geological condition for gold—shear zones, porphyry intrusions, Timiskaming conglomerate—lots of life—and my pardner and I had visions of another Hollinger or Dome. But with all the indications pointing right, there was no gold, and that little adventure cost us about a month to work it out.

So we moved further along the belt. We had lots of room, and we were beginning to feel like Robinson Crusoe

and Bill Friday. We hadn't seen a soul outside a couple of timber cruisers who had camped with us overnight down on the northeast arm of False Alarm lake.

My diary says that it was on a Tuesday, and Nature was singing "The Last Rose of Summer." My pardner and I were beginning to have visions of a hard winter—our grubstake was all shot to pieces. We had moved camp a few days before to a little lake that we had to cut portages to and that we had named Dream Lake. We had come into camp one night, tired and hungry as a couple of bear cubs, and I mixed up a bannock for supper that was a little "raw," and that night my pardner dreamt that he had feet of clay, and that his hands were kneading golden dough. He told me this and when I started to laugh he wanted to lock horns with me,—and him usually so good natured. It sure had made an impression on him, and I began to think it time we were getting back to civilization; he might get worse.

"Yes," he told me, "you may laugh at my dream, but there's something to it, Alf, and I'll know the place if ever we come to it. Why, I have that little lake pictured in my mind like a photograph. I can see the creek running into it from the West, and a big spruce swamp behind. I can see some low, woody, ridges rising to the south and I can still see that big black bear, backing me off the cliff and as I slide, pulling the roots up here and tearing the moss off there. I land up against a shear zone running through the draw, and just as I'm wading into a real gold camp, you have the indecency to wake me and tell me it's my turn to light the fire—and it raining!"

Well, to get on with my story, as I said before it was a Tuesday. The day before, we had taken our tarpaulin for a lean-to, a blanket apiece and enough grub for overnight, intending to scout around the south. We were in a country that had never been travelled except for an occasional Redman, who had put in an odd blaze where he had set deadfalls for fisher and marten and an odd snare for a bear or lynx. We hadn't seen much to interest us in the way of rocks and we were on our way back to where we had left the tent on Dream Lake, travelling a different route from the one we came. My pardner was going ahead carrying the pack and the axe, cutting an odd little tree out of our way. I was coming behind with the canoe.

Suddenly he stopped and looked around. Then he turns to me, and says, "When did we pass here, Alf?" I tell him we have never been here in our lives, and just for fun I say "but maybe this is where you were in your dreams, the night you ate that raw bannock!" "Looks like the place," he answers, with never a smile.

Soon after, we see the shimmering of water through the trees and we are glad to get into the canoe and paddle for a change. We are a little better than half way up the points to the cliff at the end of the Lake, and tells me, that's where he had the argument with the black bear. I happen to look over to the west and sure enough, there's a little creek coming in and a big black spruce swamp behind it.

We land where we think is the best place to take through the woods for our camp, which must be close by.

I am busying myself fixing the paddles and the tumpline, getting ready to pack the canoe. As the sun is getting low, my pardner has taken his axe and his prospecting pick as soon as we landed and headed for a low-lying hog'sback, to the side of the draw.

"Alf!" I hear him call me, "come over here. Bring the gold pan with you." I get the pan out of his pack, and am soon over to where he is digging in like a ground-hog, the moss, sand and rusty schist flying in all directions.

"This stuff looks like it should carry," he tells me. "Look how decomposed this quartz and schist is, and there's that green stuff we seen in Porcupine, and them sulphides—see how fine they are." And with that he takes the pan and fills it full of that loose, rusty, decomposed schist and quartz and goes down to the water to pan it, while I take a walk around to look at the formation.

I soon see we are on a shear-zone—but we have seen shear zones before this summer, and all dead ones at that. I walk a little piece farther and pull off the moss from an outcrop of quartz porphyry, and I soon see there is some volume to it, and just as I am tearing the moss off some conglomerate—the Timiskaming kind, with the red and black jasper pebbles in it—I hear my pardner shout, "Alf, come over here!"—and the way he says it, I know he has struck something. In about two hops, steps and a jump I am with him and looking into the gold pan, and I don't need the little magnifying glass to see a tail of considerable fine gold and some fairly coarse nuggets trailing behind.

Neither of us says a word; we just shake hands which means more. Finally, my pardner suggests putting up a discovery post, and as it is getting towards sunset, we figure we had better head for our camp before it gets dark.

As there is no trail and we don't know for sure just how far it is to Dream Lake, we put in an odd blaze as we go, and we have the setting sun to guide us. Just as he goes down, we see the prettiest of pictures, which I venture to say, Bill, has looked good to you many's the time when you were packing through the woods with no trail a lake. This lake is our own Dream Lake and our camp is just round the point, and to tell the truth, Bill, we done some great dreaming round our camp-fire that night.

The next morning we started in to size up the country close around the discovery. We felt we were pretty safe from being stampeded, away back there. We made sure we were getting the "heart" of the "break" before we ran a line, and then we staked a claim each—four hundred acres—which we figured would make a good enough proposition for any big operating outfit if it was any good at all.

Well, we spent about a week, staking, running picket lines and blazing well our lines, making good posts and taking no chances on some tinhorn making trouble for us by filing a dispute. We also uncovered in several other places, "showings."

About this time our grubstake was all in, so we beat it out to record, taking a few grab samples with us.

Well, we got outside and secured our claims, and that night at the hotel we met the field engineer for the Pioneer Exploration Company of London, England. We gave him a working option on our claims for one year for one hundred thousand dollars each. At the end of the first six months if they decide to go ahead, we will each receive our first payment of ten thousand dollars, and the balance will be spread over a period of two years.

How's that for the first attempt, Bill? Hoping you have had just as good as summer as your friends,

A. Hustler and Will Makegood.

## NEW GENERAL MANAGER OF BRITISH AMERICA NICKEL CORPORATION

In the re-organization of the British America Nickel Corporation that preceded the recent resumption of operations at its various plants, there have been a number of changes of personnel. Senator E. N. Rhodes, who was formerly President and Managing Director, is now President and chairman of the Board of Directors. The position of Managing Director has been abolished. Mr. E. J. Carlyle has resigned from his position as manager of the smelter at Nickelton. Mr. Charles A. Rose has been appointed General Manager. As Mr. Rose is not so generally known in Canada as in his native country, the United States, a brief resumé of his professional experience will interest the "Journal's" readers.

CHARLES A. ROSE

Mr. Rose was born in 1879, and at the age of twenty-three graduated from the University of Nebraska as Bachelor of Science. He engaged immediately in chemical and metallurgical practice, which he has followed ever since. His first position was as chemist and mill superintendent for the Alder Creek Gold Mining Company in South Dakota, which he held for two years. He then spent six years as chief chemist of the Boston and Colorado Smelting Company in Denver, and after that, two years as metallurgical engineer with the American Smelting and Refining Company. From 1911 to 1916 Mr. Rose worked on

the development of the Chuquicamata plant of the Chile Exploration Company, as assistant to the consulting engineer, being immediately in charge of the experimental operations. In 1916 he was appointed consulting metallurgical engineer to the Guggenheim Brothers, the Chile Exploration Company and the Braden Copper Company, a position he still holds. At the same time he was appointed assistant to Mr. E. A. Cappelen Smith, Vice-president of the above Companies, which position he left to accept his present appointment.

Mr. Rose comes to Canada to apply commercially a metallurgical process that has wonderful possibilities, some of which have been demonstrated with very hopeful effect during the research work of recent years. The ore he must use is, however, not so rich as that of the two competing companies, and it will require all the skill he has developed during his years as a successful metallurgist and administrator to overcome this inherent difficulty. His temerity in tackling this task is admirable, and the "Journal" wishes him a full measure of success.

### LETTERS FROM READERS

#### Mr. Ledoux Exposes False Statement about Labrador Gold

To the Editor,  
Canadian Mining Journal,

Sir,

Mr. Lloyd Roberts, under date of "Ottawa, May 5th," has sent to the New York World a communication about Labrador gold which appeared on the front page of the World's news section yesterday. There are several columns about this alleged discovery of gold in Labrador, illustrated by a map and by photographs. It is intimated in the article that there are at least 100,000 men who are waiting an opportunity to rush into that region and locate claims on the basis of the discovery by Henry C. Bellew and Richard W. Edwards of very rich gold in a certain stream. The World publishes, on the strength of Mr. Roberts' statement, an alleged certificate of Ledoux & Co. date August 19, 1921, in which Ledoux & Co. are made to certify that we extracted 5 ozs. of gold from 25 lbs. of Labrador gravels; that we gave to Mr. Bellew or Mr. Edwards \$78 in payment for the gold after deducting our charges.

I write to say that Ledoux & Co. never made this assay nor did we ever receive any such sample from Mr. Edwards or Mr. Bellew or anyone else, and that, in so far as connecting our name and a certificate alleged to be signed by us with this assay is concerned, the statements are untrue. We have been besieged by people from Canada and the United States with inquiries as to the correctness of this statement and in each case have told the facts, but this does not overtake the advertisements circulated by the promoters and others, as evidenced by Mr. Roberts repeating the erroneous statement in the Sunday World of yesterday.

We have seen both Mr. Bellew and Mr. Edwards and they have admitted to us that neither of them ever received such an assay from Ledoux & Co. They claim that the sample was assayed for them by somebody else and that it was "an error" to couple our name with it. We have asked the company promoting the chief enterprise in that section to cease using this false report, but apparently it is difficult to bring about.

We do not know whether there is any gold in that section or not, and would not intimate that there is no gold there, but feel that it should be publicly known that, in so far as investments and the rush of prospectors have been influenced or may be influenced by a statement that Ledoux & Co. have assayed such a sample, the truth should be known.

A. R. Ledoux,  
President of Ledoux & Co.

New York,  
May 7th, 1923.

### LIFE SENTENCE SUGGESTED!

When a high official of a company organized to demonstrate another of those "greatest placer fields" intimates that an alleged discoverer of at least a portion of those placers might properly be "associated" with "some other person serving a life sentence", it is in order to keep your ear to the ground.

Something has happened! Recent developments admittedly impelled the official quoted to express his sentiments.

Meanwhile a veteran mining man, who actually visited the placers and who is identified with another company that makes no preposterous claims, had an experience. Hearing of a pretentious office on St. Catherine street, Montreal, where a window bestrewn with dollars bills typified only the initial output of the placers, he quietly sauntered in and displayed the keenest interest. He was assured that Monte Cristo and Colonel Sellers were "pikers" in comparison with the men who found and who hold these very placers. Incidentally he was handed a report on the placers—over his own name.

"Do you know this Engineer who made that report?" inquired the florid visitor.

"Oh, yes", rejoined the glib salesman.

Explanations ensued—with expletives. The Engineer demanded that the faked report be suppressed. And yet the "life sentence" remains in suspension.

\*\*\*

This unauthorized use and abuse of a report upon the placers obtained by a reputable Montreal Stock Exchange firm is deserving of exposure. The report dealt with the situation as it is; traces of placer gold at various points warrant the thorough tests contemplated.

The Stock Exchange firm, having acquired extensive areas, seemingly well-located, is about to send a fully-equipped expedition to the field. No nuggets from the Klondike or elsewhere have been dangled before a gaping crowd.

The firm sent a mining man and he says he found placer gold at various points. How great is the alluvial area, is something to be determined, as well as the average value. The Montreal Stock Exchange firm has indulged in no flights of fancy. What funds they have sought will be devoted to those determinations so necessary in order to prove whether the placers are isolated patches or at all consistent over a large acreage. So, the rebuke administered by the mining man who reported for the firm might well have received a measure of publicity comparable with some of the advertisements forecasting possible millions or billions—but within the law in the event of failure. Premier Taschereau has an opportunity to make an example of someone.—Alexander Gray.

# The Mine Explosion at Cumberland

CIGARETTE SMOKING RESPONSIBLE. RECOMMENDATIONS BY MR. WILKINSON

In his report on the explosion that took place on the 8th of February last in No. 4 Mine, Cumberland (Canadian Collieries (D) Ltd.), resulting in the loss of 33 lives, Mr. George Wilkinson, who was appointed to make a special investigation, describes in detail the underground conditions prior to the disaster, the occurrence itself, the efforts made at rescue and the experiences of those who engaged in this work, gives his opinion of the probable cause of the outbreak and makes some recommendations of importance.

No. 4 Mine, it is said, is very extensive, having been in operation for twenty-five years, and consists of two haulage slopes, which converge at a point about 50 feet from the portal. The explosion was in No. 1 Slope "in what is known as No. 2 East Section, off No. 4 Slope, No. 15 West Level." The accident of the 30th August, 1922, in which 18 lives were lost, took place in No. 2 Slope.

## Ventilation

The ventillation of No. 4 Mine, it is stated, is maintained by two fans, each slope having a separate intake and return airway. For No. 2 Slope there is a Sullivan reversible double inlet fan, with a rated capacity of 180,000 cubic feet a minute against a six-inch water gauge. No. 2 slope is taken care of by a 108-inch double inlet reversible Sirocco fan, which, running at 250 revolutions a minute, has a rated capacity of 200,000 cubic feet of air a minute, against a 6-inch water gauge.

The actual quantity passing in No. 4 mine in January 1923, was 157,500 cubic feet of air a minute. The amount in the return in No. 1 slope was 79,000 cubic feet a minute. At the head of No. 4 slope, No. 15 west level, there was passing from the intake, 42,000 cubic feet a minute. This is divided in two splits, No. 1 split on the west side, in which there was passing 16,000 cubic feet a minute, and No. 2 split on the east side, through which there was passing 15,500 cubic feet a minute.

In describing conditions underground after the explosion, it is said that no damage was found until the overcast below No. 2 west level, No. 4 slope, was reached. This overcast is constructed of 10" x 10" beams, laid in mortar and cement, and reinforced with steel rails on the bottom, and in addition to the ends being supported by concrete walls, two bridge sticks of square timber are erected, one on each side of the track to support the span; these bridge sticks were knocked out by the force of the blast travelling up the slope, and the beams of which the side were constructed were dislodged, as though they had been shaken apart by the concussion. This overcast was not in use but had been built in preparation for changes to be made in the ventilation at a future date. There were four stoppings in the different roads in the vicinity of this overcast, and only one was damaged, which is taken to indicate that the force of the blast was well spent when it reached this point.

## Victims of Afterdamp

Five hundred feet further at No. 1 east counter-level, a stopping was destroyed. Sixty feet below this there was a cave which extended on the slope for 160 feet, and also continued into No. 4 west level for approximately 30 feet and into No. 2 east level, which is almost opposite No. 4 west level, for approximately 75 feet. At the inbye and of the 160 foot cave on the slope, there is a flat where a fault was encountered. On this flat a siding is made. On this siding a number of bodies were found, all having been overcome by afterdamp. These men had worked further down the slope and had travelled distances varying from 800 to 1100 feet.

No. 4 west level was caved to a point 30 feet from the end. At the entrance and partially under the cave two bodies were found. The level was caved in two other places, but beyond this there was no further damage. Here were found other victims of afterdamp. Mr. Wilkinson commends the devotion to duty of Messrs. A. W. Watson and James Pinfold, who led a number to safety, and later returned to assist in rescue work.

## Point of Origin of Explosion

Dealing with No. 2 east level off No. 4 slope, where the explosion originated, it is explained that the section at first was opened on the pillar and stall system; but about 400 feet in the coal got thinner, and the long wall system was adopted, four places being carried, which gave a length of face of approximately 170 feet. A barrier pillar varying from 50 to 70 feet of solid coal is left between this section and No. 1 east section. The cave on the slope extended into this level for 75 feet. There were evident signs of violence at the entrance, all cars having been carried forward by the blast and piled in a jumbled heap. A counter to the main slope was driven for some distance, and a heavy stopping built of 10" x 10" beams laid in mortar and cement was blown out and carried down the counter slope.

Under the heading, "deductions as to point or origin of the explosion", the report says: — "The lines of force and conditions found indicate the point of origin as being behind the pack wall of the rise side of No. 2 East Level. No men escaped out of this section. Survivors from all other parts give testimony that it did not originate in any of the other sections. A short review of the conditions existing in the sections prior to the explosion will support the theory that the rise side of No. 2 east Level was the point in that section where the explosion originated. Explosive gas had been found and reported on the rise side of this level, intermittently for over two weeks, and had existed there, practically steadily, for five days prior to the explosion. Evidence given at the coroner's inquest by the firebosses in charge of this section, if correct, would indicate that the amount of gas in this particular place at times assumed serious proportions."

### Explosive Gas Present

Extracts then are given from the evidence of firebosses as to the amount of gas in the section in question, and it is stated that "a careful perusal of this evidence indicates that for 16 hours prior to the time of entry of the shift during which the fatal explosion occurred, conditions in the immediate vicinity of the face of No. 2 East Level were not very good. The night shift fireboss states he found explosive gas seven or eight feet back from the face. He also admits firing a shot in this place, and he had not examined the place farther than the high side, where the men were working. He further states he did not know how far back the explosive gas extended, as he did not examine the place far enough back to ascertain the exact condition.

"The morning shift fireboss gives very conflicting evidence. First he states there was only a cap of gas; then he admits explosive gas was found eighteen inches from the roof, behind the cogs, twelve feet back from the face. In further cross examination he states he got explosive gas five and one half feet from the floor, and the place was nine feet high. This would give explosive gas three and one half feet down from the roof in the cavity. From a sifting down of this evidence it can almost be conceded that there was, on the average, a depth of approximately two and one half feet of explosive gas in the higher part of the roof line behind the cogs in No. 2 east Level on the morning shift prior to the explosion.

"Taking an average of two feet of depth at the cavity, and making calculations from the detail plan where this body of explosive gas would tail out on the level, there would be approximately two hundred and thirty six cubic feet of methane exclusive of any that may have existed in the vacancies in the packwall at the time the morning shift fireboss made his examination.

### Point of Origin of Explosion

It is on the return side of where this gas was reported that the body of a Chinaman, Jung Tow, was found, and all the lines of force of the explosive blast radiate from this point. After carefully reviewing all the conditions as found after the explosion and conditions prior to the explosion in this section and the circumstances surrounding the location of Jung Tow's body, I must conclude that the point of origin of this explosion was in the return airway from No. 2 east level, in the place where the body of Jung Tow was found.

Discussing the possible cause of ignition, Mr. Wilkinson eliminates naked lights, for none was used; the firing of shots, for none was fired for some time prior to the blast, and also the possibility of an electric spark, as there was no such power within 500 feet of the face or within 640 feet of the point of origin of the explosion. He says that the most striking feature in No. 2 East Level, in the search for a possible source of ignition, is the location of Jung Tow's body. This was the last body recovered. In this connection the report continued.

### Smoking Caused Explosion

"There can be no legitimate reason advanced for his being where he was found. He was right in the return airway on the high side of the packwall, and also on the return side of the accumulation of explosive gas reported. There was absolutely no reason why he should be there, except for some illegitimate purpose,

and it is just the place where it would be expected to find a person who had some illegitimate act in mind, such as smoking, as he was in a place where no one except the fireboss could be expected. The fireboss or any other person entering the level would come along the roadway, and Jung Tow behind the pack would hear them as they went along the level and he would have ample warning of their approach. His position behind the pack wall and in the return was such that any smell of smoke would be carried into the old workings of No. 1, East section, where there would be no likelihood of detection. There was no incriminating evidence found on Jung Tow's body or by a cursory examination in the vicinity of the body; but the writer was so impressed with conditions observed surrounding this body that he requested that a thorough and diligent search among all the debris be made. In compliance with this request a gang of men were put at work to move and thoroughly search among all the debris. This was done by moving all the larger pieces and putting the smaller through a sieve, with the result that after three men had worked for two days and five men for three days, a match with just the head burn off and a piece of paper similar to a cigarette paper were found about ten feet from the body of Jung Tow.

"After the whole situation and circumstances surrounding this accident are reviewed, and careful thought given to every possible angle, indications are, that the cause of ignition was a match lighted for some illicit purpose, close to where the body of the Chinaman Jung Tow was found, in the return air from No. 2 East Level, and in the vicinity of where explosive gas was known to exist."

### Portable Gas Mask Recommended

In regard to mine rescue apparatus, it is pointed out that 19 out of the 33 who lost their lives succumbed from the effects of the afterdamp, some being within 70 feet of safety when overcome.

"It would appear", Mr. Wilkinson proceeds, "that if any large effectual life saving is to be done, it will have to be through some type of portable apparatus that can be carried around by a miner and donned quickly after an explosion occurs, in a manner similar to that employed by the soldiers at the front. An apparatus of this kind would be ineffective in an atmosphere where the oxygen content is completely destroyed or very low; but in the case of the escape of men from districts that have not been affected, except possibly by a limited quantity of smoke or afterdamp, it would be very effective. With some portable apparatus of this type, it is highly probable that 19 of these men would have escaped from this explosion, as no doubt the oxygen content was sufficient to sustain life. Good work is done by rescue crews equipped with a larger type of rescue apparatus. But by the time crews are organized and equipment transported to the scene of the accident, valuable time is lost, and employees who have been uninjured by the explosion rush out to try and reach safety, with the result that many are overcome by the deadly afterdamp. In rare cases rescue is effected where men have stayed in their working places or near the face."

It is given as an illustration that the men in the Cumberland accident who were overcome and lost their lives probably reached the place where they fell within five minutes after the blast; while to get the rescue ap-

paratus from the station, organize the crews, and reach this point, which was some  $2\frac{1}{2}$  miles underground, about two hours was required. If the portable mask, called the "Self Rescuer", which is now being thoroughly investigated by the Department of Mines, can be perfected and if it will last, say, for one hour in an atmosphere containing afterdamp but within sufficient oxygen to sustain life, a similar loss of life might be avoided. Mr. Wilkinson observes that the British Columbia Department of Mines is to be commended for its prompt action in investigating the possibilities of this mask.

### Fireboss' Reports not Complete

The investigator makes some strong comments on the reports of firebosses. He says that in most cases, the report will read "Explosive gas found, etc." No idea is given as to the quantity found. If a gas cap is found, the report will read "found gas cap, etc." No idea is given as to the size of the cap or the percentage of methane that may be travelling in the air. The report adds, "From the evidence given at the Inquest it is apparent that the officials actually in charge of operations at the faces do not give enough serious thought as to the danger of allowing miners to continue at work at the face when accumulations of explosive gas are present in the vicinity. This was brought out very plainly at the inquest by the cross-examination of the fireboss in charge of this district. The evidence of the fireboss on the morning shift would indicate that there was at least two hundred and thirty-six cubic feet of methane, the inner end of which was within twelve feet of the working face, when he visited No. 2 East Level on one of his rounds, yet he admits in his evidence that he allowed the men to remain at work. What the conditions were during the afternoon of the explosion unfortunately cannot be ascertained. It would seem advisable that in a place where conditions arise such as those in No. 2 East Level, no one but the most skilled and careful miners should be allowed to work.

"It has been already demonstrated both at this explosion and the one previous that small accumulations of explosive gas are very dangerous in this mine when working on the long-wall system, as no doubt the explosion is fed by gas drawn out of breaks in the roof, which are incapable of examination.

"If the evidence of the two firebosses as given by themselves at the inquest is to be credited, it is very apparent they are not making reports showing the actual conditions, and these reports are misleading to their superior officers. Some of them are not carrying out the provisions of the 'Coal Mines Regulation Act' at times regarding blasting. The night-shift fireboss admits in his evidence that he fired a shot on the high side of No. 2 East Level, at half-past four on the morning of the 8th February, and that after firing this shot he found explosive gas about twelve feet away, and he further admits he did not examine so far back before he fired the shot. The 'Coal Mines Regulation Act' requires that he shall examine all places contiguous thereto for a radius of twenty five yards."

### Smoking in the Mines

In regard to the carrying of matches and smoking material in coal mine workings, Mr. Wilkinson observes that a package of cigarette papers, two boxes of matches, and later a burnt match were found in the mine and during the time of rescue operations. One of the bodies was picked up by Inspector Jackson. Both,

however, were discovered at points that had no bearing on the explosion. There were two convictions against employees charged with having matches and smoking material in their possession in this mine during October and November, 1922. One received a sentence of 30 days and the other three months imprisonment with hard labour.

Mr. Wilkinson adds: — "The practice of employees taking matches and smoking material into the different mines in British Columbia is becoming so serious that some drastic measure will have to be taken to stamp it out. There were light convictions at the Cassidy mine, operated by the Granby Consolidated Mining and Smelting Company, during 1922, and the maximum penalty was a fine of ten dollars and costs. Six of these eight were caught on one day — the 10th November, 1922. In addition to these at Cassidy, there were the two mentioned at Cumberland, three at Coal Creek, and one at Nanaimo. When occasional searches result in finding so many miners carrying matches and smoking material, it is safe to assume that on the many that were not searched during the year there would be a great deal more of the same material carried."

### Stricter Enforcement of Law Advocated

The report then proceeds to give in statistical form figures of the prosecutions and penalties for the offense in question recorded during 1922. It is shown that in that period there were 14 convictions, one being against an oriental, one against a coloured man, and 12 against white men. In 1923 up to date, it is shown that there have been a number of serious offenses against the terms of the "Coal Mines Regulations Act", most of them having to do with the carrying of smoking material and matches while at work in a coal mine. Three orientals and eight whites were convicted. Special reference is made to the case of Louis Hadevis who was caught recently smoking underground at Lantzville, and whose conduct was investigated by Mr. W. H. Wall, the latter holding a commission under the Act. It has been recommended in this case that Hadevis' Coal Miner's Certificate of Competency be suspended for two years.

"From a perusal of the list of offences," Mr. Wilkinson says, "it would appear as though surprise searches should be made at frequent intervals and offenders prosecuted. The maximum pecuniary penalty allowed by the 'Coal Mines Regulation Act' is ten dollars for any other person than an owner, agent or manager. From this pecuniary penalty it jumps to imprisonment, if the Court is of the opinion that the case is one that was reasonably calculated to endanger the safety of the persons employed in or about the mine. The maximum pecuniary penalty allowed is too small for serious offences, and it would appear an amendment to the Act should be made fixing a higher pecuniary penalty, as a fine of from one to ten dollars seems almost to condone an offence. When the fact is considered that many lives may hinge on a single match in the hands of an ignorant or careless person, it would seem that provisions should be made for the infliction of stiffer pecuniary penalties."

### Minor Officials Negligent

Under "Safety Measures", Mr. Wilkinson continues: — "The Canadian Collieries employ a safety engineer, who is a First Class Certificated Colliery Manager with some twenty-seven years' experience in official capacities. His duties consist of making a monthly examination of all the mines and works operated by the

company and making a report direct to the General Superintendent on the conditions found and any recommendations he may have to make to safeguard operations. He has no other duties, his whole time being devoted to safety measures.

In addition to the safety engineer, there is an efficiency committee at each mine who make an examination of the underground works and report conditions found and make any recommendations they may have for further safeguarding operations. This efficiency committee is composed of workmen and is chosen by the employees of the mine, but it is paid by the company. There is also a gas committee appointed by the employees of the mine under the terms of General Rule 37, Coal Mines Regulation Act, to make an inspection of the mine on behalf of the workmen.

"The above-mentioned were all making regular inspection of the mine and posting reports. It seems deplorable that such an accident should occur when so much effort is expended by the management, in co-operation with the Mines Department officials, on safety measures; but these committees and the safety engineer, and also government inspectors, only see conditions as they are at the time of their examinations, and the fact remains that dangerous local conditions can arise in almost any mine in a short time, and it is really the official locally in charge of a portion of the mine where dangerous conditions may arise, and the workmen themselves actually working there, who can really safeguard operations the most and can apply safety measures by withdrawing from any dangers that may arise or by taking no risks when dangerous conditions exist. In a mine the size of this one, where it will take a person from three to four days to visit all the workings, there are times when the management must rely on subordinate officials assuming some responsibility, and they are dependent on the reports of these officials to keep them in touch with conditions. These officials, who are in touch with conditions at the faces daily, are the ones who can apply the real safety measures, coupled, of course, with the co-operation of the miners themselves. When a local official finds explosive gas and is so indifferent in his duties that he does not try to ascertain the extent of the gas and yet goes out and makes a report of what is supposed to be the true condition, or when he fires a shot without first making a proper examination of a place, he cannot be said to be carrying out safety measures in the spirit shown by his superior officers. The general safety operations can be taken care of by the management, but it is an utter impossibility for them to take care of all local contingencies that may arise. A careful checking up of the various reports made reveals the fact that explosive gas or even a trace of gas had been rarely found in No. 2 East Section until a short time prior to the expansion."

#### Recommendations

Mr. Wilkinson's concluding remarks and suggestions follow:—"The most of the accidents occurring in the coal mines of British Columbia are readily traceable to laxity or indifference on the part of the officials locally in charge of the workings, or to the employees themselves. It may be charitable to give verdicts of accidental death, misadventure, and error of judgment, but the fact remains that they could better

be classed as downright carelessness or indifference. With the object of eliminating to some extent the indifference and carelessness now displayed in the frequent violation of certain rules and regulations, I would respectfully recommend that: 'the Coal Mines Regulation Act' be amended to increase the maximum pecuniary penalty for violations, to one hundred dollars instead of ten dollars, as at present.

"I would further recommend that regulations be prepared and issued by the Department of Mines to standardize the form of fireboss reports, so that the conditions in regard to inflammable gas will be described by a compulsory statement, in cubic feet, of all explosive gas found; and that the length of gas caps to be stated in inches or fractions of an inch."—R. D.

#### INDUSTRIAL ITEMS.

Little Tugger Double Drum Hoists, designed especially for the operation of scrapers a "slushing" underground, are described in Bulletin 4056-C, just issued by the Canadian Ingersoll-Rand Company and available from them on request.

Mr. Vincent Woodbury has recently been appointed agent for the sale of the Ontario Wind Engine and Pump Company's products in Northern Ontario, where

VINCENT WOODBURY

there is a widening field for the materials the company can provide for the use of the mining industry.

Electric hoists and overhead travelling cranes are described in a new catalogue, No. 480, just published by the Link-Belt Company, and available on application to the Canadian Link-Belt Company, Toronto and Montreal. These hoists and cranes are eminently suited for use in metallurgical works and mills.

## Quebec's Gold Movement Has Substantial Leadership

By ALEXANDER GRAY

There is substance and international interest behind the Quebec gold movement. That may not mean, nor should it mean, the flotation of more companies than mining share markets can digest, along with what already is quoted. The very fact that wise capital and competent technical control have combined to prove the Quebec fields, and to do it quickly and quietly, is the more reason why it should not be assumed that every prospect is pleasing. Several properties have furnished preliminary evidence of real worth, both at depth and on the surface, widths and values so far as determined having confirmed the optimistic views of the original owners; consequently there is no doubting that this is Quebec's year. But still there is danger that missteps may confuse the issues and retard initial operations.

Doubtless the new Quebec field will survive in any event—there will be mines there. Kirkland Lake surmounted early indiscretions. The inactive areas of Porcupine and the more easterly sections have a past from which they are just beginning to recover. While it is not to be presumed that there will be no indiscriminate appeals to the public in the present case, the very fact that Quebec is in a position to profit by experiences in Northern Ontario sustains the impression that mischief will be minimized by the fact that a large part of the holdings is in the hands of experienced mining investors, well able to develop an outcrop to the producing stage.

It is deserving of repeated mention that Quebec has now the advantage of all the former studies in economic geology in the gold areas undergoing exploitation, and we have the assurance of outstanding authorities that the favourable rocks are strongly developed — more so, perhaps, than they are elsewhere. This has proved to be an attraction to discriminating mining investors.

### Indiscriminate Promotions to be Discouraged

Premier Taschereau has made it clear that over-speculation will be discouraged. His Government will endeavor to meet the transportation situation. The aim of Quebec is to secure and hold for Quebec the business resulting from developments. To that end certain influential bodies concur in the temporary arrangements for roads that will make the field more accessible. Canoe routes will serve as auxiliary avenues by which supplies can be taken in. Roads are essential for the heavier hauling. Combined land and water facilities from Ville-Marie and the Transcontinental railway are counted on to meet all present and prospective requirements. When developments are further along, a northern extension of the railway from Quinze lake is not unlikely.

To a certainty the Quebec Government will not neglect their rights and opportunities. Meanwhile a railway from the Temiskaming and Northern Ontario line will tap the Kirkland and Larder districts and will lessen the labor of getting in supplies from the Ontario side. Quebec will not hesitate about railway

transportation when the business offered demands railway facilities. Besides, the Des Quinze power development should serve to attract capital to the new mining field.

International capitalists are giving Quebec's gold fields a most auspicious start. London and New York are represented in the queue awaiting the break-up. Sentiment is decidedly more favourable than when Porcupine was being unceremoniously condemned and Kirkland ignored. Unscrupulous promotions will not hold the entire field in this case, as they have threatened to do on former occasions. Popular levies, as distinguished from private enterprises, have created very few genuine gold producers in the North Country. Closer organizations equipped with sufficient initial capital will hasten the establishment of the Quebec fields.

### The First Gold Prospects Now Revived

Dr. Cooke has defined the potential Quebec country as a "band about five miles wide north of the Keewatin-Temiskaming contact." Porphyry intrusions have been noted outside this prospecting area. Masses of favorable intrusives are known to exist in townships nearer to the Transcontinental railway than those dealt with by Dr. Cooke. The fracturing accompanies the intrusions. Appreciation of Quebec has been long-deferred since Mr. Obalski wrote in 1906:

"Near the height of land, at the head and east of Lake Opasatica, prospectors found a sample of very remarkable quartz, weighing several pounds and showing coarse gold. Some work was done which justified the purchase of two blocks of mining lands from the Government and fine samples of quartz, showing gold, were produced with the applications. The discovery was made by Messrs. Alphonse Ollier and Auguste Renaud, who purchased a block. A second block was bought by Mr. D. M. Morin who transferred it to the King of the North Gold Mines."

Montrealers predominated in those organizations. The pioneers had two lakes named after them. Lake Fortune was rather a misnomer, and the King of the North remained storm-bound. Latterly, however, responsible men have undertaken to unwater the Lake Fortune and to test thoroughly the workings, which are understood to have been in the basalt. The porphyry in that vicinity is known to carry values. What is in store for the King of the North remains to be seen, as the original owners are scattered and data scarce. The shear zones of that vicinity appealed to Dr. Cooke. They are extensive. Other shear zones in Boischatel and the mineralization observed, in conjunction with information from Rouyn township, confirm the judgment of Dr. Bancroft that the rocks should be fine-tooth-combed.

### Big Mining Interests in the New Field

They will be. Should those who have entertained the Lake Fortune Mine proceed, a local laboratory, similar to the Temiskaming Testing Laboratories at Cobalt, may be equipped, and would be a convenience.

Undoubtedly the holders of the Cockeram ground will have their own special facilities, for they are well able to meet every requirement and commitment. The same is true of the owners of the Powell areas. They have a temporary mining plant on the premises. Because of the apathy or antipathy of responsible Canadians, Americans are in control of the Cockeram and Powell, where values and widths thus far are very encouraging. Moreover, these Americans have had prolonged experience as executives in the mining industry. Their present reticence conveys its own meaning: they are "Missourians", but are eagerly seeking "more of the same, thank you." In the hands of these men the Cockeram-Powell line is safeguarded from premature explosion. They cannot mislead themselves and yet they were the first to assert "Quebec has a gold field." The La Rose company has a place in the popular zone. Crown Reserve did not accept the Lake Fortune, but it is in Rouyn township, along with its neighbors from Cobalt. Messrs. O'Brien and Williams are in the north-east corner of Rouyn and at Pancake lake with the Coniagas.

As for Boischatel, it is largely held by certain of the most influential factors in Canada. Last fall it was realized that the porphyries are well-defined in Boischatel and that the shear zones there are extensive. The porphyries were traced to the northeastern corner of the township, to the granite, and they have been located further north. One block of claims was staked straddling a porphyry mass that appeared to be approximately sixty chains in width. Ottawa and Sault Ste. Marie people hitched onto this large block, because of the shearing and geology as described by Dr. Cooke. The representative in the field of some of the principals in the Cockeram-Powell section has staked between the large block mentioned and the Lake Fortune-King of the North properties. Senator O'Brien's party is understood to have located next to the three-thousand-acre block and the Ottawa-"Soo" people. These respective interests are not contemplating immediate operations in share markets. They are entering upon a campaign of prospecting.

#### **Rapid Development Assured**

Evidence accumulates that London and New York will become more familiar with the Quebec country as developments proceed. Already there are inquiries from some of the mining groups. It is the participation of experienced mining capital from the States, and the acquisitions of the Coniagas, Crown Reserve and La Rose companies in Rouyn township that guarantees authentic information in the course of a few months. When Crown Reserve and the Coniagas went into the Pancake Lake district, they helped the Associated Goldfields of Larder Lake over the stile. Even Associated may win a credit mark, although the discussion at the recent annual meeting of the company, about making a market for some shares at 30 cents, hardly harmonizes with the official statement of "assets" and the nominal capitalization of \$30,000,000.

Primarily the decision in Quebec rests with the clusters of claims staked by the Cockerams, Powell, St. Louis, Horne, the Murrays, and others, in Rouyn township. These claims have passed into competent hands—Thomson and associates; Hammell and associates; O'Brien & Williams, Fred. Connell and associates; the Coniagas, La Rose and Crown Reserve. Central Boischatel township has a similar combination of interests.

The break-up is with us, and the starter is in the stand.

### **THE MOND PROCESS AND SOCIALISM**

In a debate in the British House of Commons recently on the socialisation of "the instruments of production and distribution," Mr. Philip Snowden referred incidentally to the case of chemical workers, and he received from Sir Alfred Mond a particularly effective reply. In contrast with Mr. Snowden's airy descriptions of the idle rich who live on the industry of the workers—based, we believe, on a purely academic acquaintance with the British workshop—Sir Alfred presented an instructive piece of actual industrial history in the following terms: "It is now nearly fifty years since two young men, with very little money, decided to start a new enterprise. Their capital was insufficient, but their optimism was very great. They adopted a process entirely unknown in this country. They asked people who knew the industry to come in, but could not induce anyone to share the risk. They struggled on, and they founded a concern that has given good wages and good conditions of labour for fifty years. Those young men were my father and Sir John Brunner. That enterprise could never have been commenced under any socialist system I have ever heard of." It is just that ambition which led Dr. Ludwig Mond and Sir John Brunner to found the great concern associated with their names which the socialist system so confidently recommended to us would kill. If private capital is to be abolished houses bought by the workers and the costly furs in which Labour M. P.'s wives now appear will have to be included in the "pool." When Sir Alfred reminded the House of this result the Labour members shouted "No." Of course. Socialise capital as much as you like so long as it is somebody else's capital. When wealthy Labour leaders set the example of sharing their possessions with their poorer brethren instead of always seeking to reform mankind at other people's expense, their doctrine of "all for each and each for all" may begin to sound more convincing.—The Chemical Age.

### **SPANISH FERTILISERS**

Preparations are in progress for the exploitation on a large scale of the potash deposits near Suria, in the Province of Lerida, Spain. A Belgian concern is now building an immense plant, which it is said, will have a productive capacity more than equal to the total Spanish consumption. The product is already being placed on the market, and it is thought that Spain will soon cease to import potash fertilisers if production in Lerida is increased as expected.

Experiments have been carried out at Caceres, in super-phosphate works belonging to the Union Espanola de Explosivos, for the purpose of determining what use can be made of the low-grade phosphates that are rather abundant in the Spanish deposits. If the results obtained in the laboratories are confirmed in practice, it is reported that several million tons more of this fertiliser will be made available for Spanish consumers.

It has been announced that producers of sulphur in the United States and Italy have agreed to fix the price of sulphur in concert from time to time; also to fix the annual production to that required by the world's market, and to delimit the markets of each in a general way.

# Mineral Production of British Columbia in 1922

FINAL FIGURES EXCEED PRELIMINARY  
ESTIMATES

The total value of minerals produced in British Columbia in the year 1922, according to the final revised figures issued by Hon. William Sloan, Minister of Mines, was \$35,158,843, compared with \$28,066,641 in the previous year, an increase of \$6,092,202, or approximately 25 per cent. With the exception of the years 1916, 1917, 1918 and 1920 the past year's output in point of value was the highest in the history of the industry in British Columbia, and is evidence of the increasing development of the mining industry in the Province.

A preliminary report issued at the end of the year indicated that the output would be valued at slightly over \$32,162,000, but the final figures showed this estimate was too modest.

The output of the various minerals and the value thereof in the years 1921 and 1922 show the growing importance of the industry. The comparisons follow:

effect of this movement has now become apparent in the disappearance of the surplus stocks of the metals and the revival of a demand market at a living price.

We now hear that some of these copper companies have prepared and others are preparing to start up again, which is a sign tending to optimism for the future of the copper market, which reached 14 cents during the opening months of 1923 approached 15 cents.

The copper output for 1922 was 32,359,896 pounds, valued at \$4,329,754, a decrease from last year's output and below the normal output of the Province. This is largely due to the fact that the mill of the Britannia Company, one of our largest producers, was burned in 1920, and the new mill, only now completed, was not available for operation during the year.

## Lead and Zinc

During the most of the year 1921 there was no demand for lead or zinc, and these metals in the refined

The report contains a mass of interesting statistical information, together with the reports of the various district mining engineers on their respective districts outlining progress of development work and prospects. It is most comprehensive and illustrated by many excellent illustrations.

In summarizing conditions during the past year it is said that the increasing production shows that normal conditions in the industry are returning and may be expected to remain. As Europe is still the chief metal market and consumer, industrial conditions there regulate consumption. In spite of unsettled conditions there, the demand is good, and with the reduction of stocks on this continent, which in 1921 was greatly overstocked, metal prices in 1922 have been materially higher than in 1920. For instance, in 1921, the average price for silver was 62.65 cents compared with 67.52 cents last year; for copper, 12.50 cents compared with 13.38; for lead, 4.54 cents as against 5.73; and for zinc 4.65 cents compared with 5.72.

## Copper

During the past year costs of mining, including wages and supplies, have been materially decreased, so that the outlook for the next year's mining is somewhat brighter, and a reasonable margin of profit seems to be assured to the producers. During 1921 all the copper producers of this continent, by concerted action, reduced their output to about 25 per cent, or shut down entirely, so as to reduce stocks of copper on hand. The

state accumulated at the Trail smelter to an extent that prohibited the further purchase of their ores by the custom smelters, from which cause many of the Sloean mines were shut down. During the latter part of the year the Trail smelter was fortunate in finding an outlet in the Orient for the greater part of its accumulated lead and zinc stocks, which again permitted prompt cash payment for ores of these metals to be made, and thus started up the mines in the Sloean, so that 1923 sees these properties working again on a normal basis.

In 1922 the output of lead was 67,447,985 lb., having a value of \$3,480,316, an increase of 26,045,697 lb., or 63 percent over 1921, chiefly due to renewed activity of the Sloean mines.

The production of zinc in 1922 was 57,146,548 lb., valued at \$2,777,322, a decided increase over even the preceding year, amounting to 2,727,1176 lb., or over 15 percent. The greater amount of this was mined at the Sullivan mine in East Kootenay and concentrated and refined at Trail.

## Coal

The collieries of British Columbia held their own, having made a net coal production of 2,511,843 tons (2,240 lbs.), as against 2,483,995 tons in 1921 an increase of 27,848 tons, equal to about 1.1 per cent. With the exception of the year 1920, the net coal output for 1922 is larger than any other year since 1912, or of any previous year except 1910. There was 4,435 tons of coke produced in the Coast District by the Collieries.

The Anyox smelter converted some coal into coke for their own use.

The Crow's Nest District produced 41,400 long tons of coke, of which about two-thirds was used in Canada and one third exported to the United States.

The aggregate of the values of British Columbia colliery products in 1922 was \$12,880,000, this being less than the gross value of this year's metalliferous products, \$19,596,657.

It is noteworthy that the Northwestern District produced 67.7 percent of the tonnage of ore mine in British Columbia in 1922, carrying about 55 percent of the total value of the metalliferous output of the Province.

### The Mining Districts

The following table shows the number of mines that shipped during the year 1922, the districts in which they are situated, and the tonnage produced in each district together with the number of men employed, both above ground and underground.

|                                                                                  | Tons of Ore Shipped. | No. of Mines shipping. | No. of Mines shipping over 100 tons in 1922. | Men employed in these Mines. |        |        |

### The Colliery Districts

Coal production, the bulk of which was the product of Vancouver Island mines, leads all inerals in point of value. The gross output in 1922 was 2,580,915 long tons, of which 69,072 tons were made into coke. These figures show an increase over 1921 of 11,276 tons gross and of 27,848 tons net. Coke totalled 45,835 tons, a decrease of 13,599 tons from 1921.

A summary of the coal output gives the following figures:—

|                                 | 1921      | 1922      |
|---------------------------------|-----------|-----------|
| Vancouver Island . . . . .      | 1,625,931 | 1,754,656 |
| Nicola District . . . . .       | 183,153   | 270,890   |
| Crow's Nest . . . . .           | 759,755   | 554,361   |
| Omineca . . . . .               | 800       | 1,008     |
| <b>Total mined</b> . . . . .    | 2,569,639 | 2,580,915 |
| Made into coke . . . . .        | 85,644    | 69,072    |
| <b>Net production</b> . . . . . | 2,483,995 | 2,511,843 |

The net coal production for 1922 was 27,848 tons more than in 1921 and greater than in any year since 1912 with the exception of 1920.

The report states:

"The greater part of the gross Provincial production is still being mined by three companies—the Crow's Nest Pass Coal Company of East Kootenay; the Canadian Collieries (Dunsmuir), and the Western Fuel Corporation of Vancouver Island, which mined, collectively, 72 per cent of the gross output.

"Of the other collieries; in the Coast District, on Vancouver Island, the Pacific Coast Mines, Limited, now in liquidation, mined no coal, but recovered 4,752 tons of slack from one of the old dumps at the Morden mines; the Nanoose Collieries, Limited 99,049 tons; the Granby Company, from their colliery near Cassidy, produced 276,919 tons; and King and Foster conducting operations at the Old Wellington, made a production of 9,148 tons. In the Nicola Valley section of the district the Middlesboro Colliery Company mined 69,330 tons; the Fleming Coal Company, 38,485 tons; the Princeton Coal & Land Company, 19,418 tons; the Coal-mont Colliery, 142,806 tons; the Chu Chua Colliery, 618 tons; and the Community Coal & Coke Company Limited, 233 tons of coal.

A new coal field has been opened up in the Omineca District, where two small collieries are being developed on the Telkwa River. The Aveling coal mine shipped in 1922, 669 tons of coal and the Telkwa Collieries 339 tons, making a total for that section of 1,008 tons of coal. For convenience this has been included in the Coast District figures.

"In the East Kootenay District, in addition to the Crow's Nest Pass Coal Company, which produced 508,339 tons, the Corbin Coal & Coke Company produced 46,022 tons.

"The collieries of the Coast District, including the Nicola-Princeton and Telkwa fields, are to be credited this year with about 78 per cent of the total coal output. Of this gross amount there was sold for consumption in Canada 1,397,918 tons; sold for consumption in the United States 762,118 tons; sold in other countries, nil; making the total coal sales for the year 2,160,036 tons of 2,240 lbs.

"In addition to the coal sold, there was used in the manufacture of coke 69,072 tons, and used under companies boilers etc., 205,529 tons; while 175,719 tons was lost in washing and screening."

The reports by district engineers give interesting details of production of existing mines and the developing of properties to the stage of production. The famous Portland Canal section is especially reported upon, and the enormous development there, especially on such properties as the Premier Mine, is outlined.

The total value of the mineral production for all years up to and including 1922 is put at \$769,418,462, of which placer gold aggregated \$76,542,203; lode gold, \$416,621,913; coal, \$213,768,000; coke, \$24,520,567.—R. D.

"Stainless silver" is reported as the latest addition of Sheffield cutlers to their long list of inventions. If, as reported, the new alloy fulfils the "sterling" qualification of 92½ percent silver content, and yet remains bright for two years without polishing, it will rival stainless steel in its application to domestic economy.

# THE MINING DISTRICTS

BY THE JOURNAL'S CORRESPONDENTS.

## ONTARIO

**Power** — The Northern Canada Power Company, which has acquired the Quinze power in Quebec, has lost no time in making preparations to deliver power to Porcupine at the earliest possible moment. Immediately the lease was signed, contracts were let for the building of a one hundred and twenty mile transmission line, with steel towers, and some contracts have also been let for construction work at the power site. The undertaking is completely financed and officials of the company state that they will be delivering power to Porcupine not later than the fall of 1924. The power officials are also of the opinion that, given the ordinary amount of rain during the coming summer and fall, the present plants on the Metagami River will be able to carry the camp through the winter. The Sturgeon Falls plant, however, is not yet in commission and is not expected to be until after the flood water is over, so that it is altogether likely that another shortage will occur next winter. With the assurance of plenty of power in the immediate future, however, this will not be as serious as similar shortages have been in the past.

**Porcupine** — The talked-of strike in Porcupine did not materialize and mines are working on a normal basis. The parade on Mayday was very poorly attended, only about four hundred mine workers being present out of approximately three thousand in the camp, and most of these were back at work the next day. The mines are rapidly getting back to normal conditions and McIntyre is treating approximately 1000 tons a day for the first time in its history, which will aid materially to the output of the camp. Several hundred more miners are needed, but men are rapidly drifting back and it is possible that no great difficulty will be experienced for some little time, especially as additional miners can, no doubt, be secured from England. A recent report of the Ontario Mining Association, covering the nationalities of the men in all the principal mines of the Province, disposes of the claims of labor leaders that a very large percentage of the workers are of foreign extraction, and will, no doubt, be of great assistance to the companies in their efforts to bring in men. The report shows that Canadians and British workers constitute 61% of the total number employed, while 37% is drawn from eight different countries. Of these, Italians constitute 9.2% of the total, Finns 7.8 per cent, Poles 7.6 per cent, Slavonians 4.2 per cent, Austrians 4.1 per cent, Americans 1.4 per cent, Russians 1.3 per cent, Rumanians 1.2 per cent, while all other countries contribute 2.3 per cent.

Recent developments at the Vipond property in Porcupine have been very encouraging and the directors are considering the re-opening of the mill. During April a new vein was encountered on the 400-foot level which has been drifted on for a length of 180 feet, and

shows an average value between \$16.00 and \$20.00 across widths from 5 to 12 feet. Cross-cuts are now being driven on the 300 and 500-foot levels to intercept the same ore-body, and if the vein is found to maintain its widths and values, the mill will be started. The company has developed a considerable tonnage of comparatively low-grade ore, but with the new ore-body to raise the general average, it is believed that a grade can be obtained that will justify the mill being opened.

The Schumacher is making another distribution of assets, amounting to 17 cents a share. The money is derived from the payments received from the Hollinger on account of the purchase price of the property.

The Hollinger has declared the regular dividend of 1 per cent. payable May 21st to shareholders of record May 3rd.

Diamond drilling has been started on the Keora property and this will be followed by a campaign of underground exploration. Engineers are now on the ground making ready for this. Arrangements have also been made to start work on the Ankerite. The property has been closed down for several years, since the option on it was dropped by the Coniagas.

On the 1875-foot level of the No.9 vein of the McIntyre, some of the most spectacular ore ever discovered in Porcupine has recently been found. The high-grade is confined to a narrow quartz section about six inches in width, which runs several thousands to the ton.

**Kirkland** — A special meeting of the shareholders of the Teck-Hughes was held a few days ago to pass by-laws permitting the directors to acquire shares, bonds and debentures in any other corporation having objects similar to those of Teck-Hughes, or to carry on any business capable of being conducted so as directly or indirectly to benefit the company, and granting them use of the funds for that purpose. This particular by-law will permit the directors to conclude the negotiations for properties similar to that of the Orr Gold Mines without the legal difficulties that arose in that case. Further by-laws permit the directors to fix their remuneration and all salaries without any further specific assent of the shareholders; authorize the directors to borrow money on the credit of the company; permit the directors to pay dividends out of the funds of the company, notwithstanding that the net assets of the company may be thereby reduced to less than the par value of its issued capital stock.

**Cobalt** — It is learned that silver has been encountered in the Colonial shaft at a depth of 930 feet. A vein was encountered in cutting the station, and in the first round of the drift leaf silver was found. Sufficient work has not been done yet to determine the

value of this discovery, but it is particularly important as it opens up a possible new section.

**Larder** — At the Crown Reserve property in Larder Lake, the No 2 vein has been encountered in the cross-cut from the 550 foot level and shows a width of 14 feet, which runs from \$7.00 to \$14.00 a ton. This is not the main vein of the property, and the latter will be out very shortly. The development of this property has been very encouraging and it gives every assurance of being a profitable producer. The company has not yet taken any action regarding a milling plant, but if the developments on the 550-foot level bear out the results on the upper levels, this matter will, no doubt, receive consideration in the near future.

## QUEBEC

**Travel Routes to the Rouyn-Dubuisson Gold Belt.** — There is considerable discussion as to the best routes to follow to reach the Dasserat-Rouyn-Dubuisson gold belt, which has come to such prominence since the discovery of gold in Rouyn township last fall. In view of the importance of the development, especially in Rouyn, and, judging from the heavy demand for prospecting licenses, in view of the impending rush to numerous points along the belt, a few words on each of the principal routes to follow may be of interest.

**Extent of the Belt.** — In his report on the geology of "Temiskaming County, Quebec", (G.S.C. Memoir 86, '918), Dr. M. E. Wilson states that the belt of rocks of the Pontiac series, the equivalent of the Temiskaming series of Ontario, is 110 miles long and extends from the Ontario-Quebec boundary east to lakes Christopherson and Matchimaniou, the headwaters of the Bell river. The zone most favourable to prospecting, comprising this belt of sedimentaries and the Keewatin volcanics to the north of it, is believed to have an average width of 10 miles.

The mineralized area can be approached on three sides from railways. To the north, following a nearly parallel course at distances varying from 20 to 40 miles, runs the northernmost transcontinental line of the Canadian National Railway; twenty-five miles west of the western extremity of the belt is Dane station on the Temiskaming and Northern Ontario Railway; while to the south, navigation on Lake Temiscamingue joins the Kepawa branch of the Canadian Pacific Railway and the head of the lake, which is only 60 miles from the belt. The C. P. R., it is said, will have completed by next September its Mattawades Quinze branch, bringing its terminus to within fifty miles of the mineralized region.

For the present, prospecting activities are centered in Rouyn. This township is 35 miles south of Macamic on the C. N. R., 45 miles east of Dane, on the T. & N. O. Ry., and 60 miles north from Lake Temiscamingue.

**The Route From Ville-Marie.** — The choice of a travel route to the mineralized area depends altogether upon which section of the 110-mile stretch one wishes to examine.

During the past winter prospectors that came into Northwestern Quebec were men from Ontario; they came by the way of Dane to Larder Lake, thence with dog teams over the winter road used by lumber crews.

While this was a good winter route, the road is much less suitable for summer travel.

During the coming season the quickest way to get to Rouyn will be by motor boat via Lake des Quinze. As soon as river conditions permit, a dependable transportation service will make regular trips from Ville-Marie to Rouyn. A company has been formed to cater to the traffic. Transportation will be by automobile from Ville-Marie to Gillies Bay, a distance of 24 miles, thence by motor boat by Lake des Quinze and Kinojevis river to Pelletier landing in Rouyn township, a stretch of 80 miles. From Ville-Marie to Rouyn the trip will be made in twelve hours.

The prospectors wishing to explore the central portion of the belt will be landed by motor boat at the portage to lake Vaudray, or on lake Kinojevis if they care to canoe up the river to Clericy township or beyond.

Ville-Marie, the county town for Temiscamingue county, has a population of 840. It is the most important center on the Quebec side of Lake Temiscamingue. A mining claim recording office has now been opened there.

**The Opasatica Route** — When navigation closes next fall it is expected that the North Temiscamingue-Lake Opasatica route to Rouyn will be completed. This route, with a length of 57 miles, will thenceforth be used in summer as well as in winter.

**Routes from Ontario** — If one does not care for the comfort and rapidity of motor boat navigation as offered by the Ville-Marie route, one can reach the promising belt of the Temiskaming sediments by various canoe routes. The western end of the area, Dufay, Dasserat and Boischatel townships, is accessible from North Temiscamingue by way of the Blanche river; from Larder Lake, by Raven lake; and from La Sarre by lake Duparquet. Dufresnoy and Rouyn townships may also be reached by canoe from La Sarre.

**Proposed Road from Macamic** — Much has been written lately in newspapers about a projected road from the C. N. R. station Macamic to Rouyn township. Macamic, the nearest railroad station to the camp, is 35 miles distant directly to the north. The intervening country has been scouted and it is reported that the ground is favourable for the building of a good road all on solid bottom and without heavy grades. As the construction of such a stretch of road through virgin forest is expensive it should not be expected that it will be constructed before more is known of the probable importance of the Rouyn camp.

**From Villemontel and Amos** — To reach the headwaters of the Kinojevis river one could make use of the advantages of motor boat transportation as far as the portage to lake Kewagama by leaving the train at Amos, in preference to portaging to the Kinojevis river over the Villemontel road which is only partly completed. The Villemontel route is a good colonization road over the greatest part of its length, but the lower part is only used as a winter road. Most probably it will be completed during the coming season.

**The Harricana Route** — South of Amos the Harricana river offers a long stretch of still water navigable

by boat. Gasoline launches can be hired to travel to lake La Motte or to lake de Montigny in Dubuison township, where development work has been performed on some interesting prospects. At Amos there is a government office where prospector's certificates may be obtained.

The little town of Nottaway should be made the starting point of parties desirous of examining the unprospected eastern end of the sedimentary belt, especially Louvicourt and Marrias townships. From the headwaters of the Bell river, going by the way of Victoria Dept, 40 miles up-stream, parties could readily reach Sabourin and Bourlamaque townships, the headwaters of the Harricana river, and proceed westward without difficulty.

### NORTHERN MANITOBA

The Bingo Mine at Herb Lake in Northern Manitoba is now equipped with a complete plant for mining operations, which has been furnished and installed by Engineering Equipment Company, Montreal. Mr. Joseph Meyers, managing director of the company, has stated that no mill for treating the gold ore will be installed until sufficient ore has been blocked out to ensure a steady supply, and until thorough tests have been made to show exactly the milling equipment required. The shaft, which is now 200 feet deep, will be sunk to 400 or 500 feet, and drifting will be commenced immediately to explore the vein system on the 200-foot level.

The Luleo property at Rice Lake, now controlled by the Selkirk Gold Mines Co. with headquarters at New York, is already equipped with a stamp battery, and it is proposed to operate this during the coming summer as well as to explore further the veins disclosed on the claims.

### NOVA SCOTIA

**Mabou Mine to be Operated.**—It is stated on good authority that the Mabou coal mine in Inverness County on the west coast of Cape Breton has been sold to a company that intends to open it up and tunnel through to other underlying seams. It has been known for some time that A. J. Tonge, formerly of the Dominion Coal Company, was trying to interests English capital in the property and it now looks as if he had succeeded. The public press has stated that "the taking over of the property is conditional on the Government building a short railway." There can be little truth in this statement, for no one believes that the Government intends to build a railway for any coal company. A short spur of railway may be built to one of the near-by harbours. Mabou mine, however, is only a short distance from the Inverness Railway. Besides this it has a short line of its own running to tide-water, where coal can be shipped all summer in small schooners. But if the mine is to be a large producer, a more practical and permanent means of transportation will have to be found.

Heretofore lack of capital has handicapped the development of this valuable property. The company that opened it up was financially weak. It is understood that the company now about to take it over is capitalized at two million dollars.

The mine is under water and has been so for a number of years, but it can easily be pumped dry as the

workings are not extensive and do not hold as much water as some of the large lodgements at the pumping stations of the Dominion collieries. The inflow of water at no time was great and if pumping facilities at the beginning when water first began to flow in had been adequate, the mine could easily have been kept clear of water.

There is much difference of opinion as to the source of mine water in this field. Some hold that the sea finds its way in, while others are of an opposite opinion. It is now generally believed that the "plaster" formation in which these seams lie has, at some time in the past, been dotted with small pits which became partly filled with water and debris, the water thus finding its way into the mine.

There are several seams in this field. The coal is of splendid quality, one seam being almost a semi-anthracite. Even at the outcrop it is close in texture, hard, and lustrous. Two of the seams lie sufficiently close together to be worked in the same slope or shaft. This could be done by tunnelling through, as the distance is comparatively short. The outcrop shows a very heavy pitch, but it has been found that the seam flattens quickly underground.

Not far from Mabou lies the St. Rose coal seams, which are also said to be of excellent quality. Here again the difficulty to be overcome is one of transportation, which is not insurmountable and not even a serious problem to a company with sufficient capital. Should the Mabou mines be developed there is very little doubt that within a short time the St. Rose areas would be connected, and Inverness County would greatly increase its coal output.

**The May Day Demonstration.**—Following the prompt action of the Nova Scotia Government, which by sending a number of special constables to Sydney previous to April 1st., forestalled the steel strike being fomented by the Red element of Sydney, the Immigration Department stopped Alex. Howatt, Kansas agitator, from entering Canada. He was on the programme to deliver the May Day oration at the demonstration held in Glace Bay. Resolutions threatening strike and sabotage at the collieries if Howatt was not allowed to enter Canada, were passed, but the Department was obdurate and Howatt was held. The Reds had their day, however, and marched through Glace Bay under the red flag with its blazoned motto, "Long live Communism." In all about fifteen hundred steel workers and miners were in the march. Many were foreigners from Russia and Southern Europe, and were headed by a handful of hair-brained Scots and Canadians.

**Steel Mills Continue to Run.**—The steel workers of Sydney intended to make a show of strength and to shut down the steel plant. They did not succeed, however, as only two of the departments were forced to close for the day and labour had on May Day a very rude awakening as to its fancied strength. When they reached Glace Bay another shock awaited them when they found that while the most of the mines had remained idle, the workmen preferred to be onlookers and did not join the march. Indeed, some of them openly showed their resentment of the "song of the red flag." There is little doubt that a reaction has set in among the miners of Cape Breton, and that the May Day demonstration has been most damaging to the cause of the "Workers' Party of Canada," whose whole aim is to propagate the doctrine of the destruction of life

and property, and the overthrow of the constituted government of the country.

**Law and Order Upheld at Springhill.**—In the meantime, International Officer Van Bitner of Indianapolis visited the town of Springhill and addressed large meetings there. He stated that the United Mine Workers were a law-abiding organization and were strongly opposed to the liberation of labour by force, and that the men who originated and backed up the "Red" idea were "plum crazy". Mr. Bitner stated that his visit to Springhill had no connection whatever with the disturbed state of District 26 but that this matter would be dealt with as soon as President Lewis returned from Europe. The miners of Cumberland County have now cast off all allegiance to District 26, and have notified the International Secretary of their action. Pietou County will soon take the same action. It is not improbable that some strong union officer may in the near future be sent to take over the business of the district, to run it while it is being reorganized and saved from the "Red" element.

**Union Leaders Making Trouble.**—The District Executive are not idle in the face of what is taking place at International Headquarters. They have been making ready and are stirring up the Cape Breton Locals in readiness for a strike or any other action that will suit the occasion. While doing this, they openly state through the public press that the Dominion Coal Company has violated the agreement made last August. In order to set this report at rest, the Dominion Coal Company has requested the miners' executive to point out any violation of the agreement. This should have been done previous to any statement to the press, but this is not the style of business that suits the present union officers of this District. Some grievances of a local nature were brought up, but they did not affect the agreement.

**Restriction of Output.**—A matter that affects the public is a resolution passed by one of the locals restricting the day's work to be done by a certain type of coal mining machine. Under ordinary conditions, when the market warrants it, workmen are justified in asking for an increase in wages or for a shorter working day, but to limit the day's output is another matter. It affects every coal consumer in Canada if the miners take upon themselves to say just what amount of coal should be sent out of the mines under certain conditions. This tends to produce an artificial scarcity and this feature, as the experience of the winter just passed has shown, sends prices soaring. There is no need to dwell on this; it is all too vivid in our minds.

**The Wage Question.**—While all this trouble is being stirred up between the companies and the labor organizations and between the District and the International headquarters, an immediate danger threatens the coal industry. There is now an agitation for a return to the 1921 rates of pay, the war peak wages. No other company in Canada gave such large increases during the war, and it is unfair to ask a continuation of these. Indeed it is not possible that the collieries of Nova Scotia can pay war wages and continue to operate. It would mean the closing down of nearly every colliery in the Province. If the International Executive are under any illusion as to the ability of our collieries to pay these rates, they should be advised at once of the true conditions, and be invited to investigate them on the spot. The coal companies on

their part should be willing to give every opportunity for a full and free inquiry, and disinterested officials of the United Mine Workers need not be feared. Men who are familiar with conditions of coal mining in the United States, will be quick to see the disadvantages of Nova Scotia mining and no doubt just as quick to admit them. But "while the cauldron boils" the battle should be fought and decided on the issue of fair competition, for if nature has handicapped our coal fields by unfavourable conditions, reason should come to the rescue and state just how far we are able to follow certain prescribed union regulations and still live. It should not be forgotten in summing up the situation that the coal miners of Nova Scotia are not under the disability of so much broken time, due to over development, as their American neighbors. The yearly average earnings should be taken into account, as well as the daily. If this is not done, and if wages are forced above their normal level, it will react on the average yearly income and will greatly lower it. The loss to miners will be large, but to the country it will be disastrous.

## REPORTS ON EXPLOSIVES

The United States Department of the Interior has just published, through the Bureau of Mines, Bulletin 219, "Explosives, their materials, constitution, and analysis," by C. A. Taylor and W. H. Rinkenbach, assistant explosives chemists.

No complete work on explosives, their constitution and analysis, has hitherto been published, state the authors of the bulletin. Several books that contain chapters on analysis do not cover the matter thoroughly. Methods that manufacturers, testing stations, and other agencies have developed to meet their own requirements have not been made public. The Bureau of Mines has previously issued four publications covering special phases of the subject. This bulletin is not intended to replace these reports, but rather to cover present methods employed in the industry and to include all classes of explosives and the material used in their manufacture. No sharp distinctions can be drawn between classes of explosives. Surplus military explosives, for example, may be used for blasting, just as blasting explosives, under some conditions, may be employed for military purposes. Moreover, one class gradually merges into another because of similarity in composition.

Explosives are grouped in the bulletin as dynamites, black powders, propellants, detonators, and primers. Some materials are used in practically all these groups; others in only one. To discuss all the materials that have been or that may be used and the methods for their identification and qualitative determination is not feasible, but the methods described will probably suggest ways of examining new mixtures.

The bulletin contains information regarding the handling of explosive materials; the properties and analysis of materials used in explosives; products of explosion; the thermochemistry of explosion; liquid oxygen explosives, etc.

Bulletin 219 may be obtained from the Superintendent of Documents, Government Printing Office, Washington, D. C., at a price of 20 cents.

It is reported from Johannesburg that a number of mines on the Rand are to discard amalgamation in favour of corduroy blanketing.

Canada.

### PURCHASE OF GOLD ORES

The attention of prospectors and others is drawn to the provision in the Mining Act of Ontario authorizing the Department of Mines to purchase parcels of gold ore taken out by prospectors and others in developing or working mining claims. Arrangements have been made by which such parcels of gold ore, whether large or small, will be accepted by the Temiskaming Testing Laboratories at Cobalt, and paid for according to the schedule provided for the purpose. The Laboratories are operated under the auspices of the Department of Mines.

This offers a first class opportunity for testing the value of ores on a large scale, and also of turning ore of good quality into money for carrying on further development work. By special arrangements, on less than carload lots, freight rates on the T. & N. O. Railway are reduced 50 per cent.

The Laboratories are also equipped for working out the best methods of treatment for gold or silver ores of a refractory or unusual character.

Full information as to treatment charges, schedule of payments, etc., can be obtained from the undersigned, or from A. A. Cole, Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

THOS. W. GIBSON,  
Deputy Minister of Mines.

Toronto, 12th March, 1923.

"Assay supplies of all kinds for field and mine use. Send us an estimate of your requirements and we will attach prices. Special "sheet iron gold washing pans, postpaid to any address, \$1.00."

## LYMANS, LIMITED

Chemical and Assay Apparatus

MONTREAL

## The SYLVESTER Hand Car Motor

will save  
time and  
money for  
you

Can be attached to any standard hand car.

If you are already using pump or push cars on your surface tracks it will pay you to install this efficient outfit on them.

The extra work your men can accomplish and the time saved will soon pay for them.

We manufacture a complete line of hand cars — motor, pump and push types. Our equipment is in use on every railroad in Canada and giving excellent service.

Let us send a copy of our catalogue illustrating and describing our entire line.

## Your Air Power Bills and Angle-Compound Compressors

Repeated tests have shown the superior economy of Sullivan Twin Angle-Compound Air Compressors.

**This economy is due to:**

1. Angle-compound design, with its accurate *balance* of reciprocating parts.
2. Twin construction, consisting of two complete, balanced, two-stage angle units, each capable of being run singly, at full efficiency.
3. The Sullivan unloading system. This requires operation at either full load or at no load, the two most economical points in the cycle. It consists of a total closure unloading device on the air intake, complemented by an atmospheric relief valve which pumps out the high pressure cylinder when compression stops. Sudden surges of power are avoided. The power inflow to the compressor is smooth and even at all times.

Uneven torsional strains on the machine, with the resultant current pulsations in the motor, due to unbalanced partial loads, are obviated.

Your power bill will prove the economy of Sullivan Twin Angle-Compounds.

# PROVINCE OF QUEBEC

## MINES BRANCH

Department of Colonization, Mines and Fisheries

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, etc.

MINISTER OF COLONIZATION, MINES AND FISHERIES, QUEBEC

**MINER'S CERTIFICATES.** First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is \$10 and is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

**WORKING CONDITIONS.** During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

**SIX MONTHS AFTER STAKING.** At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

**MINING LICENSE.** The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year, and a fee of \$10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days' labour on each forty acres.

**MINING CONCESSION.** Notwithstanding the above, a mining concession may be acquired at any time at the rate of \$5 an acre for SUPERIOR METALS, and \$3 an acre for INFERIOR MINERALS.

The attention of prospectors is especially called to the territory in the North-Western part of the Province of Quebec north of the height of land, where important mineralized belts are known to exist.

**PROVINCIAL LABORATORY.** Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, Montreal, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

**HONORABLE J. E. PERRAULT,**

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

# BRITISH COLUMBIA

## The Mineral Province of Western Canada

Has produced Minerals valued as follows Placer Gold, \$76,542,203; Lode Gold, \$109,647,661; Silver, \$1,111,266; Lead, \$51,810,891; Copper, \$170,723,242; Zinc, \$24,625,839; Coal and Coke, \$238,289,565; Building Stone, Brick Cement, etc., \$36,605,942; Miscellaneous Minerals, \$1,358,839; Making its mineral production to the end of 1922 show an

### Aggregate Value of \$734,259,619

The substantial progress of the Mining Industry of this Province is strikingly exhibited in the following figures, which show the value of production for successive five-year periods: For all years to 1895, inclusive \$94,547,241; for five years, 1896-1900, \$57,605,967; for five years, 1901-1905, \$96,709,068; for five years, 1906-1910, \$125,534,474; for five years, 1911-1915, \$142,072,603; for 5 years 1915-1920 \$189,922,725; 1921, \$28,066,641; for the year 1922, \$35,158,843.

### Production During last ten years, \$339,280,940

Lode-mining has only been in progress for about twenty-five years, and not 20 per cent. of the Province has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those of any other Province in the Dominion, or any Colony in the British Empire.

Mineral locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with Mining Reports and Maps, may be obtained gratis by addressing.

# Ontario's

PROVINCE OF ONTARIO

# Minerals

DEPARTMENT OF MINES

HON H. MILLS, Minister of Mines

## Mineral Areas.

Ontario, with its 40,262 square miles, contains many millions of acres in which the geological formations are favorable for the occurrence of minerals, 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver mines of Cobalt occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

## Economic Minerals.

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario:—actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluor-spar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, portland cement, brick and tile, meet every demand.

## Mineral Production.

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1921 to be worth \$48,128,387, of which the metallic production was \$27,504,202.

The following figures show the rapid growth of Ontario's mineral industry by five-year periods since 1891:

| Year.          | Value.      | Year.          | Value.       |
|----------------|-------------|----------------|--------------|
| 1891 . . . . . | \$4,705,672 | 1906 . . . . . | \$22,388,383 |
| 1896 . . . . . | 5,235,003   | 1911 . . . . . | 41,976,797   |
| 1901 . . . . . | 11,831,086  | 1916 . . . . . | 65,303,822   |

## Dividends.

Dividends and bonuses paid to the end of 1921 amounted to \$23,140,734 for gold mining companies, and \$84,388,185 for silver mining companies or a total of \$107,528,919.

## Mining Regulations.

A miner's license costs \$5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of \$2.50 or \$3.00 per acre, depending on location in unsurveyed or surveyed territory.

## Assay Office.

The Provincial Assay Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

## Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

# Serving Canada's Mining Industry

It is many years since The Imperial Bank of Canada, recognizing the importance of the Canadian mining industry and realizing the need of banking facilities for those engaged in its development, first opened a branch in Northern Ontario.

Since then the Imperial Bank's service has gradually extended until the mining interests in the rich area between North Bay and Hearst are now linked up by a complete chain of 12 branches.

This Bank's service to the mining industry is not confined to Northern Ontario alone. In all the mining areas throughout Canada the "Imperial" is rendering a valuable and complete financial service.

## :-: EDITORIAL :-:

### THE BUDGET AND THE MINER

The annual budget presented by Mr. Fielding last week contained few items that affect directly our mineral industry, and these items are, we judge, very satisfactory. The duty of six-tenths of a cent per gallon on fuel oil is designed to protect the coal operators of Vancouver Island against the competition of oil from California and Peru. As the supply of cheap fuel from these sources may last only a few years, and as the closing of collieries on Vancouver Island might cause irreparable damage, it is probably true national economy thus to aid the coal operator at the expense of the consumer of fuel.

The outstanding item in Mr. Fielding's announcement, so far as the mineral industry is concerned, is the bounty of  $1\frac{1}{2}$  cents a pound on copper bars and rods. This is to be reduced annually and expires in 1928; but by that time the manufacturer of rods in Canada from Canadian copper should be firmly established. There are at present two copper rod mills in this country, one at the Consolidated Mining and Smelting Co.'s plant at Trail, British Columbia, and the other at the Brockville, Ontario, plant of the Eugene F. Phillips Electrical Works, Limited.

The Trail mill has never been operated, due to the late slump in copper prices as well as to the mischance that prevented a supply of copper concentrate from Copper Mountain reaching the smelter at Trail. Now, however, the Copper Mountain plant is being rapidly rehabilitated by Granby Consolidated, and will be supplying copper ore to the Trail smelter within a couple of months. The Rossland mines are also ready to ship ore to the concentrator at Trail as soon as it is released for use by the completion of the new mill at Kimberley. Thus within, say, two months we should see the rod mill at Trail at work on copper made from the ore of Copper Mountain, augmented later by ore from Rossland.

The Eugene F. Phillips rod mill in Brockville will use copper from Trail as soon as it is available and thus will earn the bounty. Meantime there is no impediment to the importation of copper for this purpose, as this is provided for by the 99 per cent drawback clause announced last week.

The budget is, in general, a colourless affair. It provides no means whereby the annual deficit can be met. Canada is still living beyond her income, and our government, this year as last, has failed to make

any serious attempt to make ends meet. Nor is there any indication that it will make such an attempt. In fiscal matters there is no hint of leadership from our political leaders. They are evidently content to travel serenely along the road that leads to bankruptcy.

This is a serious problem. We have the example of Great Britain, whose burden per capita is so tremendous compared with ours, to show what sound public financial methods, boldly conceived and courageously executed, can do towards the paying of national debts. Our taxes are among the lightest in the world. Our annual deficit in the national balance-sheet is trivial compared with the sum of our personal resources or the volume of our trade and commerce. It is a foolish, spendthrift course to over-expend our income, even by fifty millions a year. Our public finances present an outstanding example of thriftlessness to a people in whom wasteful and senseless expenditure is a besetting sin.

If Canadians, both in private life and in public offices, need one lesson more than another, it is a lesson in thrift. The budget of last week demonstrates a policy (or lack of policy) that is both thriftless and shiftless. It is time something was done to cope with this menace to our national solvency.

### LABRADOR EXPEDITIONS

Events of the past few weeks, as well as other events that are pending, serve to indicate that at last the general public is beginning to be suspicious of the ridiculous campaign of stock-selling conducted during the winter in the name of Labrador. Meantime several hundred thousands of dollars have been collected from the public, and no doubt have been securely tucked away for future reference by the promoters.

As the "Canadian Mining Journal" pointed out on numerous occasions prior to this silly "boom", Labrador is one of the most readily accessible of the unexplored parts of the "pre-Cambrian shield." Little is known of its geology, but that little is not unfavourable to the occurrence of economic minerals; in fact, the geology in places is decidedly favourable to the occurrence of ore-deposits. There have been determined already in the casual surveys made on the coast some areas of rock apparently of Keewatin age. — the rocks most prolific of mineral deposits in other parts of the shield. There are also intrusions of basic rocks such as caused the silver of Cobalt to be gathered

into veins. There has been little geological mapping of the coast and none of the interior. As for prospecting, the casual observation of a few explorers and brief visits from two or three searchers for placer gold in restricted localities comprise it all.

For the prospector, Labrador is literally an unknown land. Many have observed the coast along the six hundred miles of its length; few have landed on it, and these only at chosen spots, far apart. What the land holds for the prospector when he conducts a genuine search, no man knows.

The prospects of finding placer gold in paying quantities are not good, since the ground has been subjected to the same glaciation that has swept away the placers that undoubtedly existed at one time in the gold-bearing areas of Ontario and Quebec. There may be found in Labrador a remnant of these pre-glacial placers, as has been the case elsewhere; but the chances are much against it. Or exploration in the interior may disclose an area, similar to that in the Yukon, that has escaped the glacial action, though as yet there is no evidence of this. However, the fact that unglaciated hill-tops have been observed on the northern part of the coast indicates that the ice sheet of glacial times at that point was comparatively thin, and hence could be diverted with comparative ease.

If all the money that has been collected from the public in the name of Labrador were spent in expeditions to explore Labrador, we should have a fund of information about that little-known coast before the next winter makes it inaccessible once more. Unfortunately this event is far from likely. However, the money subscribed to certain of the Labrador schemes is to be honestly expended on exploration. To the men engaged in this prospecting in Labrador, the "Journal" wishes good fortune and a safe return, and to those who have backed these explorers with their money, a profitable investment.

### THE IMPERIAL MINERAL RESOURCES BUREAU

The fourth annual report of the governors of the Imperial Mineral Resources Bureau, dealing with the Bureau's work during 1922, has recently been issued. As the services of this Bureau are of growing importance to the mineral industry of Canada, it will be well to make this report the occasion of a review of its organization, objects and methods.

Among the benefits arising from the world war, none is fraught with greater significance to Canada than the general determination throughout the Empire to foster and extend inter-imperial trade, and to make the Empire, so far as possible, a self-sustaining and self-sufficient unit. The Imperial Mineral Resources Bureau was organized with the specific object of stimulating the development, for the common ben-

efit, of the Empire's mineral resources. This laudable object, previously left at haphazard, is now being pursued by a capable and energetic staff in London, who have the advice and the active aid of scores of the best brains in Great Britain, the Dominions and the Crown Colonies.

The offices of the Bureau in London are now the chief centre in the Empire for the collection and dissemination of information regarding the discovery, development and use of its mineral resources. In addition, comprehensive data are now available there concerning the world's mineral resources, this being necessary in order to gauge properly the comparative value of the Empire's known resources, as well as to provide for the most economical supply of those minerals not found within the Empire.

The Bureau collects information from all quarters of the globe, sifts and arranges it, and sends it out again in a most useful form. Its printed volumes forming the "Mineral Conspectus of the British Empire and Foreign Countries" are now familiar, in their grey cover, in every part of the Empire. The first task has been to summarize the known information regarding each of the commercial minerals. This prodigious task has been almost completed. Thereafter the information will be kept up to date by the publication periodically of volumes containing more recent information, as well as by new editions of the complete work on each mineral as occasion warrants. In addition to this Mineral Conspectus there is a statistical series giving for each mineral during the years 1919-21 the production, imports, exports and prices. Some of this series have already been issued and the preparation of the remainder is in an advanced stage. A number of volumes in the series, "Mining Laws of the British Empire and of Foreign Countries," have been printed and others are in the press or in course of preparation.

In addition to printing these works, the Bureau is now in a position to supply authoritative and recent information about the field it covers. The object is to give advice to the commercial world, to collect information for industries requiring knowledge as the possible sources of particular minerals, and to put producers of minerals in touch with consumers. There has been a large number of such inquiries during the past year.

The activities of the Bureau are guided and regulated by a Board of Governors composed of fourteen eminent men connected with the mineral industry. Canada's representative on this Board is Dr. Willet G. Miller, who is the nominee of the Federal Government. In addition there are fifteen Technical Advisory Committees, each dealing with a separate department of the Bureau's work or with a metal or groups of metals. Dr. Miller is chairman of the Committee on Nickel and Cobalt.

In order to have available recent and reliable information about mineral resources throughout the world, the Bureau has established relations with selected correspondents in all quarters, and files the information so obtained in a Technical Index, which is systematically kept up to date. In Canada the correspondents are officials in the various departments of mines, in addition to a few university professors. Correspondents have been obtained similarly in foreign countries wherever possible.

Gradually the Imperial Mineral Resources Bureau is assuming the functions and the importance of an emporium for the mineral wealth of the Empire. It holds, potentially, a position of vast responsibility, and it has commenced to fulfil its function in a fitting way. Tangible evidences of its utility are becoming more numerous with each succeeding year. Canada is supporting worthily the building up of this new Imperial institution.

### A VETERAN ENGINEER PASSES

Robert Carr-Harris died recently at his home in Bathurst, New Brunswick. With him passes one more of the few remaining links with pioneer engineering in Canada. He was in his eightieth year, and had been engaged in engineering practice in Canada since his graduation as a youth from King's College, London. While most of his practice was in the building and maintenance of railways, he became intimately known to many members of our mining fraternity, as a teacher, first in the Royal Military College, Kingston, and then in the School of Mining, Queen's University.

Though he was a man of brilliant mental attainments, Professor Carr-Harris will be remembered chiefly on account of his outstanding moral character. This was impressed, unconsciously, upon all those with whom he came in contact. He was one of the comparatively few human beings with whom conviction is synonymous with action. While far from infallible in his judgment, he allowed nothing to stand in the way of what he considered truth and justice. This at times led to self-denial that his friends considered an injustice to himself.

Professor Carr-Harris had an unusual capacity for enduring friendship, and fortunate are those upon whom that friendship was bestowed. He was a true philanthropist, in the literal sense of the word. His students and his friends might smile at his idiosyncrasies, but they could not doubt his good faith or his friendly interest.

A never-failing fund of energy and of good spirits was one of Professor Carr-Harris' most obvious qualities, until the first years of the war, when his eldest son, a doctor in military service, was killed in Egypt. From this blow he never fully recovered. He had nine sons, most of them engineers, and three daughters, by

two marriages. To the widow and the children who survive him the "Canadian Mining Journal" offers its sincere sympathy.

### THE MABOU COAL BASIN

With the prospect of a much enlarged market for the coal of Nova Scotia, substantial interest has been aroused in some of the outlying coal-bearing areas. Heretofore the capacity for production in the Sydney coal field has been sufficient for any prospective market, and as it is highly developed and ideally situated for shipment and produces coal of very satisfactory quality, there has been little incentive for the exploration and development of fields less favourably placed.

One of the coal basins of Nova Scotia of which little is known is that at Mabou, between Port Hood and Inverness on the west coast of Cape Breton Island. It is almost entirely a submarine area, lying in a narrow synclinal basin of which only the apex is exposed on land. The coal of this west coast does not, in general, make good metallurgical coke and its content of sulphur and ash is somewhat in excess of that of the Sydney field.

The Mabou mine was flooded in 1909 and has not been operated since that time. Contemporary evidence indicates that the flooding was due to carelessness and that the mine could be re-opened with little difficulty.

As the Mabou coal basin is virtually unexplored except at and near its outcrop, the natural course of events in its future development will be to resume production on the small scale warranted by present knowledge and simultaneously to explore its further possibilities. The property has been on the market for many years, and we hope that the recent public reports of its acquisition by English investors presage a resumption of activities that will result in profitable operation.

There was an interesting little item in the news from Glace Bay, Nova Scotia, last week. Silby Barrett, formerly International Board Member of the U. M. W. A. for District 26, "cleaned up" the staff of the "Labour Herald", of Bolshevik fame, with the aid of his brother. The dispatch intimates that if the "Red" editor and his staff had only been more numerous, say to the extent of a dozen or two more, a serious resistance might have been established. Mr. Barrett has made himself a fine record during recent years as a safe and sane labour leader, and now that the tide of popular sympathy in the Nova Scotia colliery districts is turning strongly in favour of the "moderates" the personal retribution meted out to the "Labour Herald" staff on account of their scurrilous personal remarks about Mr. Barrett has met with popular approval.

# THE MINE HOIST

VARIOUS HOISTS COMPARED. ELECTRIC HOIST

RECOMMENDED

BY J. A. MARSH\*

What hoist shall I use? That is the question that confronts every miner who has ore to bring to the surface. And this question has been a live, vital issue with every miner from time immemorial and continues to be a problem with most mines as long as they are in operation, and as depth increases, conditions change, or improved methods are made possible by the unending developments of mechanical progress.

**Hand Power.**—What was probably the original type of mine hoist, a primitive, home-made windlass over the pit mouth, is with us yet and will ever continue in use in remote regions for prospectors' exploratory work. The modern geared, high-power hand winch is a development from this original crude windlass and is used in many of the smaller mining operations, being the handiest and most effective mechanism for certain classes of work by reason of its light weight and the ease with which it can be transported.

**Horse Power.**—The next forward step in the evolution of the mine hoist was the horse power machine. This was in use for many years, and there is still an occasional demand for it, but it has largely dropped out of use because of its slow speed, the increasing cost of manufacture, and the introduction of other forms of power that can compete with the horse power hoist in weight and price and can easily excel it in speed. One great advantage of the horse power hoist is the cheapness of the power, and the fact that fuel does not have to be transported at great cost over difficult country, nor is it necessary to go to the expense of stringing wires for power purposes. However, in spite of this advantage in the use of horse power, the company with which the writer is connected has practically abandoned the manufacture of the horse power hoist owing to the increased cost of production, combined with the small demand, which raises the selling price to a figure higher than the average user of this class of hoist would care to pay.

**Gasoline Hoist.**—To offset this disappearance of the old-time horse power hoist, the modern small-sized gasoline mine hoist has made its appearance and is coming into favor in many kinds of small mines by reason of its low price, its light weight (making it easy to transport) and its speed and general efficiency in operation. In fact, the writer has known of this little gasoline hoist being used in coal mine work where one would naturally think of steam as being the only power by reason of the cheapness of the fuel. But, as will be noted elsewhere in this article, cheapness of fuel is not the only consideration, and even in the presence of such an abundance of potential power it is often found advisable to use power derived from some other source. These gasoline hoists for mine work are made usually in the smallest sizes only, seldom exceeding ten horse-power, and frequently much smaller, as they are designed for the use of the smaller mines only and for exploratory work, where

frequent transportation may be necessary, or for auxiliary power or special work round the larger mines.

**Steam Hoist.**—Steam power for hoisting has been in use for so many years and has proven its worth in so many and varied installations, that it is needless to give it more than passing mention here. It has been developed gradually through the years until several distinct types of steam hoists have been evolved and more or less standardized, and it is now possible to equip the mine with any size of steam hoist from the tiny ten horse-power machine right up through the various sizes of geared hoists to the mammoth "first motion" hoists in which the thrust of the piston is applied directly to the drum shaft. Many variations have been applied in the way of Corliss valves, automatic steam regulation, etc., to save the steam, give greater efficiency and minimize the wastage of power inevitable with the use of steam. But this will not be dealt with herein, as the main purpose of this brief article is to deal with some phases of a newer power which is lately displacing steam in mine hoists, viz., electricity, some of the many advantages of which are given below.

**Electric Hoists.**—In the first place, to quote an experienced mine manager who has had large experience with both steam and electric power for mine hoisting: "It is accepted that the steam economy of hoisting engines is necessarily poor owing to intermittent service." But this intermittent use of the hoist is not the only factor that tends to make steam a wasteful power for this purpose. As this same expert says: "In addition there are other causes that militate against steam economy, such as the start against full load; the rapid acceleration to full hoisting speed, requiring uneconomical admission of steam throughout practically the full stroke of the piston; the variation of load during short hoisting periods, together with the frequent stops for variable periods, during which the cylinders cool, etc." All the above mentioned conditions vary, of course, with the depth, the loads, and the type of hoist, and are minimized to some extent by the many refinements in valves, steam regulators and other devices on the larger and more expensive hoists, but which are of necessity omitted on the smaller hoists of simple valve design and low price.

The above represent only a few of the objections to steam power for the operation of mine hoists, all of which are overcome or at least bettered by the use of electric power. Some of the other points in favor of electric power for this purpose, rather than steam, are given below.

**Operation.**—The operation of an electric hoist is so simple that experience has proven that any man of ordinary intelligence can soon learn to run one, whereas an experienced man is required for operating a steam power hoist, and in most of the larger installations a man with a government certificate is required by the mining laws.

\* Secretary-Treasurer, Marsh Engineering Works, Belleville, Ont.

**Repairs.**—With an electric hoist there are no water or steam pipes to freeze and burst; no boiler tubes to burn and develop leaks in the hands of a careless fireman; no grates to burn out through neglect to remove the ashes from underneath; no cylinders or drip cocks to freeze in cold weather; no rivets or seams to become leaky when not properly cared for by the man in charge; no water or steam valves to get out of order; no water gauge glasses to break; in fact, none of the many well-known causes of repair bills incident to the use of steam power. In fact, as one electric hoist user says: "Our repairs are nothing to speak of."

**No Engines or Piping.**—By the installation of electric power the manager immediately removes an expensive item from his plant maintenance account. Only those who have had the care of engines and piping through all sorts of weather and under all the varied conditions of mine hoisting can appreciate what this means.

personal and costly experience: "Records of boiler repairs due to acid feed water are not available, but an average during my experience is that tubes in boilers must be renewed every six months, and further that constant boiler trouble results from the use of our mine water. We therefore consider that electric power is preferable." In this particular case (and there are probably many other mines situated as unfavorably, or even more so as regards their source of water supply) to procure an adequate supply of suitable water it would have been necessary to provide a pumping station and to lay from one and a half to two miles of water mains; and for a considerable portion of this distance it would have been necessary to blast out a channel in the rock to put the pipes below the frost. Under such circumstances it will be seen quite readily that the stringing of electric wires is much less costly and will give greater and more permanent satisfaction.

**The Electric Hoist Always Ready For Use.**—There is

---

A typical Electric Mine Hoist of medium size with 40 inch diameter fixed drum and 40 H. P. Electric Motor, Solenoid Brake on the Motor and Post Brake on the Hoisting Drum.

---

**Convenience Of Location.**—It is remarkably easy to instal an electric hoist. Just set it wherever you want it, string a couple of wires and make the simple connections required, and it is ready for use. There is no steam piping to instal, no condensation of steam and consequent loss of power from long pipe lines, and no bother trying to correlate the hoist and the steam supply. This convenience of location is also appreciated, perhaps to an even greater extent, when it becomes necessary to remove the hoist to another location, and this has to be done frequently at some mines.

**Boiler Feed Water Supply.**—The provision of an adequate supply of water of the right quality for use in the boiler is a vital necessity to every user of steam, and in some cases this is a very expensive item to meet. In not a few cases the main or only source of supply for this boiler feed water is the water pumped from the mine itself, and this is often so strongly impregnated with chemicals of one sort or another that it is entirely unsuitable for use inside a boiler. One mine manager reports from his own

no time wasted waiting for steam in the morning or at noon; no lost time during the day from low steam pressure, a lazy fireman, or a slow fire. There are no shut-downs from low water or any other of the many causes of trouble that occur at times in the use of steam power. With electricity the power is waiting and ready for you whenever you want to use it, ready to give you full capacity and to handle your full load at any time without warning or preparation.

**Electricity Cheaper in Operation.**—You pay for power only while it is actually in use, and the moment you cease using it your power bill stops its upward climb. When not actually hoisting, the only expense is the pay of the operator and interest on the investment. On the contrary, in using steam power the fires have to be kept burning, the boiler must be kept supplied with water; in short, with steam you are paying for power throughout the whole working day, even though it be used for only a fraction of the day. Furthermore, there is not the same tendency to wastage of power in the use of electricity as with

steam. This is more particularly the case where the boiler has to be set at some distance from the hoist, and the long pipe lines cause condensation of steam and consequent serious loss of power. As one mine superintendent has written: "We are obliged to have steam for other purposes, but if we had to carry steam any distance we would not consider a steam hoist up to the capacity of what we have." This company are using two electric hoists at their two mines, buying their power, but they find electricity so satisfactory that they say: "Even if we had the steam and were generating our own electricity we would use an electric hoist unless our boiler was close to the hoist."

**Ease of Control.**—Experience proves that the handling of an electric hoist is easier and simpler than with a steam hoist. There is no steam to condense in the cylinders, no drip cocks to look after, no steam pressure to watch, the operating levers are fewer, and many operators think the load is more easily picked up and more easily controlled in transit than with steam.

**Electricity is Cleaner.**—It is a nice thing to have the hoist room clean and tidy and to have the men in charge take pride in their work and in their spotless surroundings. It tends greatly to give men that contented, satisfied feeling that makes them permanent, dependable employees. With electric power this is much easier to accomplish than with steam as there is no water and grease dripping around, as is almost inevitable in the use of steam. This may at first sight seem but a minor matter, but on careful consideration its real importance will be more fully appreciated.

**First Cost and Operating Expense.**—First cost is, after all, a minor consideration, as the question of operating expenses is a much more important factor than the initial cost, and, as noted above, experience proves in the majority of cases that the operating expenses of an electric hoist are lower than for a steam hoist. As one mine manager puts it clearly and briefly: "We have about half a dozen of your hoists in actual use, and we are absolutely satisfied with them. We prefer electric hoisting to steam because, in our opinion, electric hoists are much more economical to use." Regarding initial cost, opinions vary as to the basis of comparison. If the boiler is included in the price of the hoist, the electric hoist is certainly cheaper—anywhere from five to fifteen per cent, depending on the make of motor used. But some claim this is not a fair comparison, inasmuch as the boiler is the power-producing plant, and it would be impossible to include the electric power-producing plant with the first cost of an electric hoist. Therefore, it is claimed by the holders of this theory that the steam hoist with its engines, but without the boiler, should be compared in price with the electric hoist with its motor, but without its power-producing plant. On this basis, with both hoists ready to receive and utilize their respective powers, the electric hoist is usually somewhat more expensive in first cost than the steam hoist, but this is soon offset by the reduced cost of operation.

**Electric Power Cheaper Than Steam Power.**—This is true for the majority of mines, and is a large factor in deciding many to instal electric hoists.

**Electricity Sometimes Preferred Where Fuel is Cheap.**—Take the case of a certain coal mine, for

instance. If there is any one place where one would naturally expect steam power to be used for hoisting, it is in a coal mine, where the abundance of cheap coal would make steam lower in price than electric power. But this coal mine (and there are doubtless others similarly situated) is now using electric power for its hoisting. After using steam hoists for a number of years and giving them a thorough test, they have abandoned the use of steam for this purpose and substituted electricity, even though they already had 6 or 8 of our steam mine hoists at work in their various pits. The explanation of this change of power is simple. First, their only source of boiler feed water of suitable quality is a couple of miles away from the mine. Second, frequent moving of the hoist is necessary, and it is cheaper to string electric wires than to lay water pipes each time the hoist is moved. Shafts are sunk 800 ft. between centres one way, and 600 ft. between lines. This gives an area of 800 by 600 ft. for each shaft. The average life of a shaft is about 18 months. When this area of 800' x 600' is exhausted, the shaft is abandoned; shaft houses, hoists and all equipment are taken down and set up at a new shaft. From these facts it will be easily seen that in this case electric power is less costly in the long run than steam, even though the fuel costs would be so low in the latter case.

As the above-mentioned coal mine has now nearly a dozen of our electric hoists in operation, their experience should be of value to others; hence, the following extract from a letter recently received from their manager will be read with interest by all mine managers who are now considering the problem of what power to use in hoisting:

"We consider electric power is preferable, due to its flexibility in the transmission of power, by stringing wires, and because changes are made from one shaft to another at less cost than would be the case if steam were used with its consequent expense for water lines, or for repairs if mine water was used. This leaves aside the question of boiler failures which used to be of frequent occurrence.

"To sum up briefly, our reasons for the change were:

1st— We installed an electric power plant primarily to operate mining machines.

2nd— Having electric current available, we changed to electric hoists owing to their greater flexibility and ease of operation.

3rd— To avoid installing and maintaining a water supply of suitable feed water.

4th— To reduce expenditure for upkeep and renewals for boiler repairs due to use of acid water. Our records show a net saving of approximately \$3000 per annum for these items.

5th— Economy in fuel, power being generated at one plant, and use of current being spread over all our operations, intermittent operation is not so important. Our central boiler plant is up-to-date as to its heating of feed water and superheating of steam, and is under skilled supervision in the use of fuel, which was not possible the case of detached small units."

The above points in favour of electric power for hoisting are not, of course, arranged in order of merit as regards their relative importance. In fact, it would

be impossible to so arrange them, since owing to the varying conditions in mines, what would be a deciding factor for one mine would be a matter of minor importance in another mine. Nor is the above an exhaustive list of the arguments in favour of the electric hoist. There are others; but it is probably better not to exhaust the subject rather than to exhaust the reader by dilating on the subject. From the information given above one can readily understand why so many mine managers, when confronted with the question at the beginning of this article: "What hoist shall I use?" are deciding in favour of the electric hoist.

### PERSONAL AND GENERAL

Mr. Thos. Riggs, who was formerly Governor of Alaska and is now vice-president of the Continental Mines, has been visiting the company's properties in Cobalt and Kirkland Lake.

Mr. A. W. MacDonald, Superintendent of the Industrial Department, Dominion Coal Company has just returned from a business tour of certain of the European countries. He reports labour conditions in some of these countries as far inferior to those of Canada, due to a large extent to the post-war strikes.

Mr. R. A. Bryce, of Toronto, has been making a trip to Porcupine and Kirkland Lake.

Mr. Horace Young has gone to Porcupine to take charge of the Moneta property.

Mr. Cyril Knight has returned to Toronto from Cobalt, where he is still engaged in his examination of the silver mines.

Mr. W. P. Alderson has left Montreal for the Quebec gold field, where he will direct the exploration of two groups of claims held by a syndicate of which he is a member.

Mr. D. H. MacDougall is in Montreal from Sydney, where he has been very successful recently in coping with the labour problem.

Mr. N. A. Timmins, on his return from London, has stated it as his opinion that the unfounded rumours about the sale of the Hollinger mine to British investors had been put in circulation deliberately by men interested in the public sale of certain Porcupine mining stocks, with a view to using the Hollinger's record to promote their sale.

Mr. Palmer J. Cook, formerly in charge of the Midas mine at Valdez, Alaska, is now superintending the operations of the Granby company on the Outsider Group, near Maple Bay, Portland Canal district.

The season's dredging in the Yukon was commenced last week by one of the Burall and Baird dredges, and the others will follow rapidly. Hydraulic mining promises to assume greater dimensions this year than last.

Two weeks ago grading was commenced on the ground where the new copper concentrator at Anyox is to be erected. Work on the new dam was resumed at the same time.

The impending scarcity of fluorspar of commercial grade has induced numerous large users on this continent to acquire deposits of the mineral for future use. Cryolite is the only alternative source of fluorine, and it is available even less readily than is fluorspar.

### NOVA SCOTIA COAL FOR QUEBEC PROVINCE

The possibility of using the coal measures of Nova Scotia much more largely than at present to supply the needs of Quebec, and possibly part of Ontario, is engaging a good deal of popular attention just now. The reported acquisition of coal areas and the express intention of the Department of Mines at Halifax to investigate thoroughly the maximum productive capacity of the province's coal measures, lends added interest to the question. In this connection it is interesting to note the information given by Mr. F. W. Gray of the British Empire Steel Corporation before the Senate Committee on Fuel Supply in Ottawa recently.

In reply to the question as to how much coal Nova Scotia could supply for Canada's need and whether coke could take the place of anthracite Mr. Gray said, "I think there would be no difficulty at all in Nova Scotia supplying all the coal that Quebec at least, and probably Ontario, would need in the way of coke as an equivalent for anthracite. I might say I have used Sydney coke all winter at Ste. Anne's. I would rather have it—much rather—than anthracite. It is less trouble; it is less expense." Mr. Gray stated further that the coke had about the same heating value, and that he would be willing to pay more for a ton of coke than for a ton of anthracite.

In referring to the possibility of the British Empire Steel Corporation establishing by-product coke ovens in Montreal, Mr. Gray stated that the investment involved would run from three to five million dollars for a sixty-oven plant with a capacity of 1000 tons of coke a day. "Of course, the old line gas plant has been entirely superseded by the by-product coke oven. You can make better gas and more of it, and get a greater recovery of by-products from the modern by-product oven than from the old-fashioned retort gas works. They are out of date. I might say, too, that there is no comparison between gas-house coke and by-product coke. In the gas works your object is the destructive distillation of coal to obtain gas; in by-product coke your object is to get a high-carbon fuel. The coke oven has, I think, entirely superseded the gas plant where coal alone is used. Water gas is a little different."

Cape Breton coal, Mr. Gray stated, would give a 64 per cent yield of coke, two or three gallons of benzole, ammonium sulphate in unusually large quantity, and tar of peculiar value. Nova Scotia coal is known to be particularly rich in by-products. It is high in sulphur, too, but this is not an insuperable objection as it can be removed economically.

The great improvement in by-product oven practice during recent years was well illustrated in the evidence. It requires no more than 100 men to run modern ovens producing 1000 tons of coke a day, which is about one-quarter the number required with older types. To-day a mechanical pusher empties the oven into a steel car, where quenching breaks it up sufficiently to discharge it on a belt conveyor, which takes it to bins or stock piles.

One of the most important effects of the use of Nova Scotia coal for domestic fuel, via the coke oven, would be the steady effect it would have on the mines, Mr. Gray explained. To supply the Island of Montreal would require a million tons a year. With this to depend upon each year, the coal operators would have what they have always lacked heretofore—a dependable market. The railway contracts for coal from Nova

Scotia are never certain, they are awarded to American mines if they can undercut our own mines in price, and the operators in Nova Scotia must meet these prices or lose the railway custom.

Nova Scotia's chief competitor is not the old producing states, Pennsylvania, Illinois and Ohio, where the cost of mining has gone up much as in Nova Scotia, but West Virginia, where coal is mined to-day more cheaply than anywhere else in the world. It is a new field with new seams. One advantage Nova Scotia does possess, however, and that is water transportation. A fair estimate of the cost of carrying to Montreal and discharging there is a dollar a ton. Eventually, after Nova Scotia has captured the whole of the Quebec market, it may be profitable to try to gain part of the Ontario market, in spite of the present necessity for lightening ship before going through the St. Lawrence canals.

"This year", said Mr. Gray, "we hope to put almost as much coal into Montreal as we have ever done. It has taken a long time to get that market back. Last year was abnormal because of the strike in the United States. Prices will be lower this year than last because coal will be more plentiful. We hope to put up the St. Lawrence nearly too million short tons this season."

### NATIONAL MINING CORPORATION IN PORCUPINE

At the annual meeting of the National Mining Corporation in London three weeks ago, the company's interest in the Porcupine gold field was discussed. With the New Consolidated Goldfields, an interest was bought in a number of Porcupine properties, one of them adjacent to the Hollinger, Mr. J. B. Tyrrell being the agent in Canada. An active search for other promising properties is to be carried on.

### CANADA'S MINERAL COMMERCE

(By Dr. Charles Camsell, Deputy Minister of Mines, in "Natural Resources.")

Canadians have long been taught and accustomed to place mineral resources in a high rank among the Dominion's industrial assets, and, on that account, perhaps the greatest surprise that greets anyone who has had little occasion to study the national trade balance is the fact that Canada is heavily a debtor country in regard to mineral products. The formidable sum of more than \$190,000,000 is the amount by which the value of exports of mineral commodities during the past year has fallen short of meeting the bill for mineral purchases abroad.

The Canadian trade returns include three broad classes of commodities which are wholly or mainly of mineral origin: (1) iron and steel products; (2) metals other than iron, such as copper, tin, and the precious metals; (3) non-metallic minerals, such as coal, oil, asbestos, glass, and clay products. It should be noted that each main class includes highly manufactured articles as well as ores and other mine products in raw state. Altogether Canada's imports under these three broad classes of merchandise amounted to roughly \$307,000,000, while the total sales to other countries aggregated about \$115,000,000. Thus on this group of

foreign commerce items there was incurred a national trade deficit of \$192,000,000.

The above figures, and those in the following table, are taken from the external trade records as published by the Dominion Bureau of Statistics for the twelve months ending February, 1923:—

| Commodity Groups.     | Imports.      | Exports.      | Favourable or adverse balance. |
|-----------------------|---------------|---------------|--------------------------------|
| Iron and its products | \$134,162,000 | \$ 47,598,000 | —\$ 86,564,000                 |
| Non-ferrous metal     | 36,684,000    | 41,854,000    | +5,170,000                     |
| Non metallic minerals | 136,955,000   | 26,017,000    | —\$110,938,000                 |
|                       | \$307,801,000 | \$115,469,000 | —\$192,332,000                 |

This net showing of Canada's commerce in mineral commodities does not appear to do full justice to the capacity of the Dominion to attract and support mineral industries of both basic and secondary character. It is true that the Dominion's mining industries have made great advances, that last year's trade does not furnish an altogether fair index, and that a large part of the huge excess of imports over exports is accounted for by heavy foreign purchases of highly manufactured goods of mineral origin. But, making due allowance for all such factors, there seems to be ample scope for efforts aimed toward strengthening Canada's trade position through the development of mining industries.

Viewed in the light of the Dominion's commercial balance sheet, it is doubtful whether any single class of natural resources now merits closer study than mineral areas as the foundation on which to build new Canadian development. Wheat lands and pulpwood areas have in turn attracted huge extensions of industry during the past quarter of a century. The growth which they have supported has vastly enhanced Canada's standing as a creditor country in regard to such commodities as cereals, lumber, and paper, but that same growth has incidentally served to accentuate very sharply the country's debtor position with respect to iron and steel goods, coal, oil, and mineral products in general.

Time and again mention is made of the remarkable rise of Canada's wheat and other cereal exports, and to the vital part they play in righting the Dominion's balances abroad. It is seldom realized that a great portion of the surplus created by cereal exports is offset by the bills for mineral purchases.

Comparing the external trade of Canada in 1922 with that of the year 1902 it will be observed that there has been a huge growth in both import and exports, but that commodities of mineral origin accounted for only about 10 per cent of the total increase in sales, as against nearly 40 per cent of the increase in value of national purchases abroad. Anyone who is at all conversant with the nature and extent of the Dominion's mineral possibilities must share the view that the course of our commercial progress in the coming years can and should be shaped in such manner as to reduce rather than to swell the annual deficit from our trade in commodities of mineral origin. So far as its facilities and resources permit the federal Department of Mines is sparing no effort to attain this objective and to bring Canada's mineral resources into greater use.

## Robinson Mine

*Chevalier d'Industrie!*

Were it the practice among Anglo-Saxons and their racial offshoots to bestow honors and titles upon other than individuals, it would be entirely appropriate to enroll the Robinson gold mine at the Witwatersrand.

Soon the Robinson will be a memory — cherished by those who knew it, appreciated its management, understood it to be one of the guidons of that gold industry, the greatest of its kind, whose technical chiefs wrote thus in their memorial to the Right Honorable Joseph Chamberlain when he visited the Witwatersrand in 1902:

"Gold-mining as a business in other parts of the world has been recognized as the acme of speculative investment. Here, though capricious as units, the mines are, as a whole, regular within certain fixed limits; and it is perfectly true that greater reliance can be placed on the continuance of the deposit than has ever been known in gold-mining, and, therefore, large preparatory outlays on the basis of a staple industry are more justifiable."

It was at the Robinson, in 1890, that the first cyanide test works established that process without which the banket ores of the Witwatersrand might not have been brought to their true destiny. In 1885 the first gold was panned from the banket conglomerates of the Rand. Two years later there was a pilot stamp mill. Three years afterward, the adaptation of cyanide to the treatment of the banket by the Robinson technical chiefs precipitated the bitter struggle with Glasgow metallurgists that resulted in a victory for the gold industry. The following year chlorination was attempted at the Robinson. Lawyers and courts contested the claims of the MacArthur-Forest people to exclusive rights in what was the practice in Phoenician times. It was life or death with the gold industry, where the ore was comparatively low-grade even though consistent.

Of the rôle played by the Robinson on behalf of the industry, through the demonstration of the efficiency of treatment by cyanide, the combined technical chiefs also said to Mr. Chamberlain:

"One of the early difficulties was the unsatisfactory extraction of gold from the ore. At first, not more than 50 to 60 per cent was obtained by the amalgamation process; later on, concentration and chlorination of concentrates improved matters; but it was not until the chemical treatment of all the sands and slimes by the cyanide process was introduced that satisfactory results in this regard were reached. Now it may be said that the average well-equipped mine can recover 85 to 90 percent of the gold contents of its ore."

That percentage upon which the Messrs. Jennings, Pope Yeatman, George E. Webber, Harry H. Webb, S. C. Thomson, G. A. Denny, Fred. Hellmann, W. L. Honnold and others prided themselves twenty years ago, would cause trouble in many a board room if not bettered to-day. Cyanide practice as further developed at the Robinson led to those supplements in modern metallurgy by means of which lower grade ores yield more and more of their precious metal contents. And it was at the Robinson that the first filter presses were introduced.

So the information that the Robinson Directors have decided to suspend dividends — only 1½ per cent on issued capital having been earned in the past fiscal year — carries with it more than a pang. The Robinson, one of the galaxy of beauties along the outcrop, is "in extremis".

The Robinson began production in 1888. To the end of last year (34 years) its crushing record was 11,500,000 tons for a total gold output of 5,723,044 ounces — approximately half an ounce per ton milled. The dividends from that tonnage totalled £11,980,938. Estimating the gold at its parity, the total production was worth approximately £24,309,946; including the premium it was worth £24,600,000, say \$130,000,000, taking the pound at \$5. About one half this grand total was expended on production, and that illustrates the benefits resultant from such mines. Nor does that include capital expenditure.

For over a third of a century the Robinson milled its millions. Beginning in 1887, when part of the farm Turffontein was acquired, it is interesting to note for the information of vendors of now-a-days that in 1889 six Main Reef claims were purchased, along with 100 acres of land, for £15,500 in cash and 3,375 shares of £1. That synchronized with the adoption of cyanide practice.

So mining engineers in all countries will pay their respects this year to the grand and glorious old Robinson.

## Labrador Misrepresentations Re-Act

Not only has one officer of a Labrador Gold company denounced an alleged discoverer of the placer fields as a man who should be serving a life sentence, but here is an admirable protest by a man who was misquoted regarding those fields, and who has the courage to tell the truth, the whole truth, and nothing but the truth:

I have been quoted in a prospectus of one of the companies offering for sale mining locations in Labrador, to the following effect: "I have spent twenty-five years of my life in Labrador region and I have seen the Indians bring down considerable quantities of gold nuggets. I am the owner of a large number of claims, which I propose working thoroughly this coming summer. None of my holdings are for sale, but I can truthfully say, secure every possible claim you can in Labrador." I wish to say that the writer of the above, to say the least, has drawn very much on his imagination. I have never made such a statement. I have not spent my life looking for gold. I do not know Labrador thoroughly; it is too extensive for one man. I do know of one Indian that did bring out a piece of gold, but I do not own one claim in Labrador, though I have had assays made here in Montreal and, very much to my surprise, did get gold, from sand taken by myself. As I do not wish that anyone should be led to purchase a claim on what I am wrongly reported to have said, will you please insert this denial in your paper. —F. C. CREAN, 234 Board of Trade Building.

The foregoing appeared on the editorial page of "The Star" of Montreal, on May 8, among correspondence.

As "The Star" was hampered by the chief culprit, the statements of Mr. Crean deserved more prominence. Who is going to run to earth and expose this whole affair, and punish whoever is guilty of wrongdoing? The Government of Newfoundland remained passive while the advertisements making all sorts of claims were enticing the adventurous public. Premier Faserchew has declared Quebec will not allow suspicious propositions to be foisted on the public. Meanwhile hundreds of thousands of dollars have been handed over to promoters, and one of the chief culprits is said to have left these parts for a healthier climate in New York.

### "Another Hollinger" — Not Quite!

An outstanding firm of Chartered Accountants certifies to the following balance sheet of **Canadian Associated Goldfields Limited**, as at December 31, 1922.

| LIABILITIES                                                                                                                                                                                                |                 |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Capital                                                                                                                                                                                                    |                 |
| Authorized 10,000,000 shares of \$1.00                                                                                                                                                                     | \$30,000,000.00 |

| As instructed we have audited the accounts of Canadian Associated Goldfields Limited, for the period from October 1st, 1921, to December 31, 1922, and have prepared therefrom the above Balance Sheet, as at December 31, 1922, which in our opinion correctly reflects the financial condition of the Company as at that date according to the best of our information, the explanations given to us, and as shown by the books of the Company. |  |

MARWICK, MITCHELL & CO.,  
Chartered Accountants,  
Toronto, April 11, 1923.

If that be a true and correct valuation of the assets of Canadian Associated Goldfields Limited, then there is no limit to the extent to which a mining corporation

can pervert the truth. According to it, the 21,934,096 shares, or trust receipts outstanding, have a face or nominal value of about 97 cents each. Private sales are reported at from 9 to 15 cents. What is the worth of an audit under such circumstances? To value the Associated properties and plant, timber and water power rights at almost \$21,000,000, is making an expensive plaything of higher mathematics. Current assets are \$164,941 less than they were in the year ended October 31st, 1921. The increment from bank balances, investments and the sales of power increased from \$35,044.21 to \$68,944.87, which is partly accounted for by the fact that the balance sheet covers a fourteen months' period. Those who know the facts hardly can concur in the opinion that the statement reflects the actual worth of properties, power and paraphernalia combined.

### WORLD'S GOLD AND SILVER PRODUCTION FOR 1922

The American Gold and Silver Institute estimates the world's gold production during 1922 as 14,841,136 ounces, valued at \$306,793,000, as shown in the following table:

|                 | 1922          | % of world production in 1922 | % of increase (plus), decrease (minus), 1922, from 1915 |

During the first three months of 1923, the collieries of the United States have produced 138,600,000 tons of coal. This is 30 per cent. in excess of the production of the corresponding period in 1921 and 1922, and only 3 per cent. less than the record year, 1920.

# The Mineral Districts of British Columbia

A DIGEST OF INFORMATION FROM THE 1922  
REPORTS OF THE RESIDENT MINING  
ENGINEERS

Figures given in the Annual Report of the Minister of Mines of British Columbia place the total value of the mineral production of that Province from 1852 to 1922 inclusive at \$769,418,462. Coal mining has produced \$238,289,565, more than any other separate class of mining; next comes copper with \$170,723,242 while lode gold is third with \$109,647,661 and placer gold fourth with \$76,542,203.

The southwestern district of the Province, including Vancouver Island and the southern mainland coast section, leads others in point of production. It is followed, in the order named, by the Northwestern, Eastern, Southern, Central and Northeastern Districts. The Southwestern and Eastern Districts owe a substantial proportion of their output to their coal mines. In other sections production is almost entirely from metal mines.

It is shown that the metal mines produced 1,573,186 tons of ore in 1922, having a gross value of \$19,231,857 and with the placer gold a total value of \$19,596,657.

## Gold

In analyzing the placer mining situation, the production from which last year shows an increase of over 56 per cent, it is pointed out that practically all the production came from the northeastern and northwestern districts. An approximate apportionment is interesting as follows: Cariboo, \$190,300; Atlin, Stikine, and Liard, \$149,000; the remainder \$23,500. In the past four or five years placer mining output has dropped from between \$500,000 to \$700,000, attributable largely to economic conditions with which all are familiar. The encouraging showing of last year is due to the production of the newly opened up diggings on Cedar Creek, Cariboo.

There was a 45.9 per cent increase in lode gold output, the Portland Canal Division, in which the Premier Mine is situated, being responsible for a gold value of \$2,553,303, or more than the remainder of the Province. The Belmont-Surf Inlet Mine produced \$725,124 and the Osoyoos Division, within which area is the Nickel Plate Mine, produced \$370,365. The Rossland Camp produced \$170,651, less than 20 per cent of normal, as these mines were shut down in March, pending the preparation of a concentrating plant at Trail.

The increase in silver output of 4,427,922 oz., is explained by the phenomenal showing of the Portland Canal Division. Of the total provincial production of 7,101,311 oz., no less than 4,264,228 oz., came from this section, practically all of which was from the Premier Mine. The Slocan's output was 1,104,628 oz., that of the Fort Steele Division, 956,028 oz., and that of Nass River, 400,000 oz.

Copper, lead and zinc already have been dealt with but it is interesting to note with regard to copper that the Granby Consolidated Mining, Smelting & Power Co. produced 93 per cent of the provincial total for 1922. The other 7 per cent was about evenly divided between the Belmont-Surf Inlet Mine, the Rossland Camp, and

the Tidewater Copper Co. on west coast of Vancouver Island.

## Non-Metallic

The production of building materials has advanced in value from \$1,903,799 to \$2,533,926. Attention is directed to the amalgamation of the two well-equipped cement manufacturing plants situated on Saanich Inlet, Vancouver Island, under the name of the B. C. Cement Co. This concern made a production last year of over \$1,000,000. On the Coast, chiefly between the Island and the Mainland, there are a number of quarries actively engaged in taking out granite, sandstone and andesite, all of excellent quality. These quarries supply the stone building material of the Coast cities and also have exported to the United States. Firebrick and lime are largely produced, and for making the latter a new and extensive plant was erected at Blubber Bay a few years ago. The limestone used is of exceptional purity. Lime and limestone values for last year are placed at \$400,864 as compared with \$299,191 in 1921. A small proportion was used as smelter flux by the Granby and Consolidated companies and a large quantity was quarried by the paper and pulp mills for their own use.

For convenience in administration British Columbia has been divided into six mineral districts and over each is a mining engineer whose duty is to assist in development by recommending, where prospects merit it, expenditures on roads and trails, and to offer advice to operators and prospectors when the same is sought. Each of these engineers is heard from officially once a year through the Annual Report of the Minister of Mines. Their comments on progress and general conditions, and their reports on individual properties, are extremely interesting in parts and certainly warrant brief review.

## Northwestern District

George Clothier, of the Northwestern District, divides his territory geologically into the "Coast Range Belt", the "Eastern Contact Belt" and the "Western Contact Belt." He states that the growing importance of the "Eastern Contact Belt" was emphasized in 1922 by the "remarkable output and profits of the Premier Mine in the Salmon River section." This mine produced nearly as much gold and nearly double the amount of silver of the whole Province in 1921. This Belt has been explored, he asserts, only in a few spots and he stresses the importance of trails to make it more accessible. "It took fifteen years," he declares, "from the discovery of the Premier until it was a producer and it therefore behooves us to look ahead that length of time in opening new fields for prospecting."

Mining has been much stimulated by the present stable or rising metal markets and more properties have been under development. Some of those upon which work is under way are cited and Mr. Clothier, doubtless having in mind the certainty of excitement and consequent speculation in the Portland Canal Division this year, directs special attention to the provisions

of British Columbia Statutes relative to the filing of prospectuses with and for approval by such companies as propose selling stock to the public, and also of the obligation placed upon one giving a bond or option on a mining property to insert a clause in the agreement that those employed on the property shall be paid semi-monthly and that security for wages shall be deposited with the Government Agent or Mining Recorder.

### Northeastern District

J. D. Galloway, of the Northeastern District, points to the development of properties on Hudson Bay Mountain, near Smithers, as one of the outstanding events of the year in that section. Most encouraging results were obtained in the operations on Dome Mountain in the Babine Range and it is becoming more evident that this is an important mineralized zone that has been little prospected. On Rocher Debole Mountain the copper properties remain inactive and the mine of that name, closed down for some years, is not likely to be reopened until the market improves. The Silver Standard Mine near Hazelton was opened for about three months and then again closed down.

The remarks of Mr. Galloway on the Cedar Creek placer mining and on the possibilities of this form of mining elsewhere in his district, are worth quoting.

A very marked revival in placer mining has been evident in the Cariboo and Quesnel Divisions. The important discovery of Cedar Creek camp (discovered in late fall of 1921) has aroused considerable interest and during the summer there was a great influx of prospectors. Much misinformation was published in the daily press about the Cedar Creek discovery and as a result many persons rushed into the country who knew nothing about prospecting or mining. Most of this type soon left the district again and spread pessimistic stories that the Cedar Creek discovery was a fake. The truth is that a strike of very rich placer ground was made at Cedar Creek and that the work done during 1922 has exposed richer ground than the discovery, and that the deposit of auriferous gravel is likely to have a considerable areal extent. Gold to the amount of approximately \$125,000 has been taken out during 1922, mainly by means of rockers, so that it is quite evident that the discovery is one of some importance. The placer deposit at this point is somewhat unusual, as it differs in many ways from the old workings of the Cariboo, and therefore should be of great value as an indicator for this section of the country and should stimulate renewed prospectings.

"Much Keystone-drilling of placer gravels has been carried out in the Cariboo during the year with satisfactory results in places. On the result of such testing will depend the future of the older and formerly worked parts of the Cariboo. It is probable that many areas of low-grade gravels will pay to work if properly handled. Placer mining of this nature calls first of all for thorough testing of the ground to determine values and physical conditions; and, secondly, for sufficient capital for the equipping of the property. Besides the operating companies there are at the present time in the Cariboo district a number of companies doing large-scale placer mining and there is still much ground left that at least warrants preliminary testing to see if it will not pay to work by dredging or other methods."

### Central District

It is pointed out by A. W. Davis that the Central District, upon the mineral development of which he

keeps a watchful eye, is the most important of the Province as a future source of non-metallic minerals. Large deposits of gypsum, magnesium sulphate, magnesite, sodium sulphate and sodium carbonate are found and some are near railways. While, with the exception of gypsum, these have not at present a large market, it is thought that the condition cannot continue indefinitely.

Mr. Davis recommends that prospectors might pay more attention to his territory with profit. He also suggests that small operators would be benefited by grouping their properties and reorganizing under one head. On Cadwallader Creek there are four small mills with a capacity of from 10 to 20 tons a day each. Were these replaced by one modern mill of larger capacity, the result would be one overhead cost instead of four, cheaper milling, and an increased saving in values.

Interest in placer mining has increased although there has been no large production. On one property, the British Columbia Alluvials Ltd., operating on Bridge River, an extensive campaign of construction has just been completed. This plant is expected to be operated successfully this year.

### Southern District

Philip B. Freeland, of the Southern or Boundary District, first refers to the fact that there was no copper production in this section last year, but goes on to tell of the prospective operation of the Copper Mountain by the Granby Company. There were 4,616 tons more shipped from the district than in 1921. The increase in output of silver and lead is accounted for by high-grade silver-lead properties at Beavercreek. These veins are persistent, a large amount of plant has been installed and a greater tonnage production this year is predicted. Regarding the Rock Candy Mine of the Consolidated Mining & Smelting Co., Mr. Freeland points out that there was a lower output of fluorspar and states that this was the result of strikes in the steel and coal industry of the United States. He adds: "The deposit at Rock Candy Mine has become siliceous in the face of the two drifts, but there is still a considerable tonnage at the lower elevations. The high silica content hinders successful concentration."

Referring to the Hedley Gold Mining Co. it is stated the mine was active the greater part of the year, that a total of 41,286 tons of ore was mined and treated, making 1621 tons of concentrate and 511 tons of arsenic, in addition to the gold content extracted by cyanidation. Operations ceased in the late autumn because the cold interfered with power generation.

### Eastern District

The silver-lead-zinc industry of Eastern British Columbia is said by A. G. Langley, engineer for that section, to be in a healthier condition than it was prior to 1922. This has been due to improved smelter rates and the acceptance of zinc ores and concentrate by the Trail Smelter. Two events are selected as of special importance, one the construction of the 1500-ton concentrator at Kimberly for the treatment of the ores of the Sullivan Mine and the other the completion and successful operation of the Silversmith concentrator at Sandon.

Increase production from the district in and around Sandon is referred to and Mr. Langley finds it gratifying to note that the old Slocan Star, under the management of the Silversmith Mines Ltd., after a period

of comparative inactivity, again has been established as the leading producer of the Slocan. He says, too, that the output of mining companies has been supplemented by that of leasers, who have been unusually active. It is pointed out as noteworthy and a fact that speaks well both for the richness of the ores and mining conditions, that ore can be mined profitably by leasers with small capital who rely on their shipments to pay good wages after deducting all expenses, including a royalty of 15 or 20 per cent.

### Western District

Wm. M. Brewer, of the Western District, mentions that there has not been much metal production in this section because the Britannia Mine was idle, the Marble Bay Mine, Texada Island, has been closed down, the Tidewater Copper Co. was inactive through lack of water for power purposes, and the Sunloch and Old Sport properties, Vancouver Island, were not developed by the Consolidated Mining & Smelting Co. This last is explained by the low price of copper.

Notwithstanding all this, Mr. Brewer optimistically points to the reconstructed Britannia plant, to the satisfactory development of the Tidewater, and to other indications in support of his belief that 1923 will see an increase in the production of copper, silver and gold. He also dwells at length on the activity of the coal mining industry of the Island.

### VOLATILIZATION OF SILVER AND ZINC

Numerous experiments with the volatilization of silver chloride from argentiferous ores have been conducted at the Salt Lake City and Berkley, California, experiment stations of the United States Bureau of Mines. In addition to experimentation on ores, research was done along physico-chemical lines. The investigations included the determination of the vapor pressure of the silver chloride at various temperatures; also an examination of the hydrolysis of silver chloride by water vapor, resulting in the formation of metallic silver. Approximate determinations were made of the equilibrium, at various temperatures, between silver chloride, water vapor, and hydrochloric acid. The temperatures at which several common minerals of silver were oxidized or disassociated were noted.

From the results of the last-mentioned experiments it seems that the roasting of silver minerals tends to produce metallic silver. Chloridizing roasting of silver minerals, therefore, is essentially a problem of chloridizing metallic silver and subsequent volatilization of silver chloride. In the furnace, conditions must be maintained that prevent the silver from being hydrolyzed and from reverting to the metallic state before passing from the ore as silver chloride during volatilization. After further study a detailed report covering these experiments will be published.

Silver is not easily chloridized and volatilized and has so far offered greater difficulty than any of the common metals. It seems extremely sensitive to atmospheric conditions in the furnace and probably is easily affected by the gangue constituents of the ore.

Silver minerals occur in many low-grade and complex ores of lead, zinc, and copper, silver sometimes being of major importance, especially in economic value. A high percentage extraction is required to make any process for such ores commercially feasible.

In many ores the silver has minor value. When silver is present with rather high percentages of lead

and copper, it may not seem economical to provide the conditions for making high extractions.

Behavior of zinc in ores treated by the volatilization process depends largely on the arrangement of the mineral in the ore, also on the atmosphere that is maintained in the furnace during treatment. Experiments have indicated that in a strictly oxidizing atmosphere little zinc is volatilized, especially in the zinc carbonate ores of the Goodsprings, Nev., district. The test of the Yellow Pine Mining Co's. ores and of other ores from the Goodsprings district were made on zinc concentrate in which the zinc ranged from 30 to 40 per cent, the silver and lead content varying from 4 to 8 ounces and from 4 to 8 per cent, respectively. The quality of silver and lead volatilized ranged from about 50 to 90 per cent, whereas the total amount of zinc volatilized generally averaged less than 1 per cent.

Analysis of the fume precipitated in volatilization tests on these ores indicated high assays in silver and lead and 3 to 6 per cent in the zinc assay.

The behavior of zinc is very erratic, the conditions under which it is volatilized probably depending largely on the sulphur content in the ore. The presence of sulphur causes a complicated series of chemical reactions during the usual treatment, consequently a variable quantity of the zinc is driven off with other volatile materials. When crude ores high in sulphur content have been treated, most experiments indicated nearly complete volatilization of the zinc, but when the ore was given a preliminary roast to reduce the sulphur content, the amount of zinc volatilized varied considerably.

The presence of zinc in carbonate ores containing silver, lead, and zinc indicates that by volatilization a clean-cut separation can be made between the lead and zinc. On the other hand, in treating complex sulphide ores much of the zinc was volatilized in nearly every experiment and was subsequently precipitated in the Cottrell treaters as chloride with the other metal chlorides.

Details of these experiments on zinc are given in Bulletin 211, "The chloride volatilization process of ore treatment," which may be obtained from the Department of the Interior, Bureau of Mines, Washington, D.C.

### COMMERCIAL PRODUCTION OF RADIUM IN CORNWALL

The commercial production of radium in England began in February with the completion of an extraction plant at the South Terras Mine in Cornwall. The capacity of the plant is reported as 300 to 400 milligrams a month. In order to reduce the bulk or the ore and lessen the quantity of expensive chemicals necessary in the process a new concentration plant is also being added to the works.

Several Cornish mines have yielded radium-bearing ores for many years, but heretofore the output was shipped to Germany and France for treatment. The principal radioactive minerals found locally are pitchblende, autunite, and tobernite, the pitchblende deposits in Cornwall being said to be richer than those of Brazil, the United States, or Czechoslovakia. If the production of radium at the South Terras property prove successful, it is not unlikely that operations looking to a larger output of these ores will be undertaken at other mines in the region. — U. S. Commerce Reports.

## A NEW COMBINED MOISTURE TRAP AND SEPARATER OF UNIQUE CONSTRUCTION

A new device which separates and discharges water from Compressed Air lines; collects pipe scale, rust and sediment, delivers clean dry air, suitable for use in pneumatic tools and other equipment, has recently been placed on the market in Canada by the Canadian Ingersoll-Rand Company. This device known as "DriAir" was invented by C. A. Dawley of the New Jersey Air Meter Co. Mr. Dawley is a pneumatic engineer of note and also invented the well known Tool-om-eter, Drill-om-eter and the New Jersey Blower or Air Transformer.

Water in compressed air is a familiar nuisance, but its detrimental effects are not always fully recognized. The water itself slows down the operation of tools, freezes in the exhaust, washes out the lubricating oil, causing rapid wear and rusting of parts, cakes the sand and chokes the feed in sand blast machines, spoils air brush painting, and in fact is a disadvantage in most of the many applications of compressed air. In addition to these troubles, the wa-

Fig. 1—Cross-section of the DriAir, showing vanes, float-valve, etc.

ter collects in pockets in the piping and, when finally picked up and carried along as "water hammer," loosens pipe scale, rust and dirt from the inside of the pipes and carries these gritty materials along into the equipment being operated.

### Why Water Collects in Air Lines

Ordinary free air, taken in at the inlet of a compressor, always contains moisture in the form of invisible vapor. The amount of water is expressed by the percentage of humidity of the air at any temperature. An actual example will illustrate how considerable a quantity of water is commonly involved. Take a compressor of 1000 feet per minute running for eight hours, intake temperature 82 F., humidity 75 per cent. The total weight of vapor taken in with the air will be 600 pounds, equal to about one and one-half barrels of water. If the air is compressed to 80 pounds pressure and not cooled by an after cooler, this entire quantity of water will go into the air lines. If an aftercooler is used and cools the air down to its original temperature, it should precipitate and collect 476 pounds of water but would still pass 124 pounds along

the lines in the form of vapor. This will be further condensed as the air cools off in the distributing lines and will show up at the outlets where the air is taken for use.

### The "DriAir" Removes and Discharges the Water

A DriAir at the outlets will separate and automatically discharge all the remaining water in liquid form. The DriAir should be installed on the branch lines as far as possible from the compressor, to give the air every chance to become cool. For this reason the DriAir is made in small sizes, even when used with large compressor plants.

The DriAir is automatic and requires no attention after installing. It drains itself by means of a float-operated valve as fast as the water collects. Separation is effected by the well known methods used in steam separators, including reduction of velocity, change of direction, baffles for collecting the entrained water and a channel or gutter to carry the water out of the influence of the current of air.

The makers claim no originality for the method of separation but only that it conforms to the best accepted practice in separator design. Tests show that the efficiency of separation is more than 99.5 per cent.

### Automatic Draining an Outstanding Feature

The great advantage of this new device is its automatic discharge action. This eliminates the necessity of a man going round at intervals to open drain valves, the supervision required to see that this is done and the annoyance and damage resulting if it is not done regularly. The DriAir combines in one device, a separator to collect the water and a trap to discharge it, both at about the price of either a good separator or a good trap alone. The DriAir, it is claimed, is not only simpler, cheaper and more compact than two units, a separator and a trap, but its action is much more satisfactory on account of entire freedom from becoming "air-bound," and other advantages shown below.

When used on steam or gas lines, the DriAir furnishes essential protection to reducing valves, regulators, meters, pumps and other equipment.

The DriAir is made in two standard sizes: for one-inch pipe, weight approximately 60 pounds; for two-inch pipe, weight 65 pounds.

### Self-Bailing Float

The DriAir is equipped with the highly ingenious self-bailing and non-collapsible copper float shown in the illustration. This float will stand any pressure, no matter

Fig. 2—Cross-section of self-bailing float

how high, for the simple reason that the central equalizing tube permits the outside pressure to enter the inside of the float. A slight reduction in the external pressure, such as occurs continually in any pressure system, will reverse the flow in the equalizing tube. Suppose a little water has accumulated in the float as shown, the outward flow through the equalizing tube will then eject the water first.

As the float does not have to sustain a high pressure, it is light and has great buoyancy. It is therefore powerful enough to operate a valve with large opening and high lift, giving a greater water discharge capacity than most steam traps of the same size inlet pipe. The mechanism is simple and sturdy and easily removable as a unit, without disturbing any pipe connections. All internal parts are of bronze or copper, free from corrosion and practically permanent. The valve seat is safeguarded from grit and dirt by its protected location, as will be seen by reference to the sectional cut of the complete device.

### ANTHRACITE COAL INDUSTRY OF WALES

The Welsh anthracite measures furnish almost the entire supply of this coal in the United Kingdom. All the anthracite fields in Wales lie in the mining district of Swansea (in western Glamorgan, Carmarthen, Becknock, and Pembroke Counties). An official survey of these measures made in 1904 for the Royal Commission on Coal Supplies reported the total amount of anthracite coal in sight as 6,310,292,214 long tons.

The South Wales anthracite measures have not been widely developed, owing to the limited demand, especially in the domestic market. Anthracite consumption in the United Kingdom does not exceed 2,000,000 tons per annum, and a large part of this is used in the marking of gas and in malting. The use of anthracite for domestic heating is very limited; nor does it appear that there will be in the near future any great expansion in this last use, as the British people seem (from long custom, perhaps) to prefer an open soft coal fire.

#### Production and Export Trade

The following table shows the output of anthracite coal in South Wales in the years 1912 to 1922, the amount of this output exported, and the percentage of exports based upon output:

Output and Export of Welsh Anthracite Coal

| Year           | Output<br>Tons | Export<br>Tons | P. C. of<br>export |
|----------------|----------------|----------------|--------------------|
| 1912 . . . . . | 4,353,010      | 2,355,718      | 54                 |
| 1913 . . . . . | 4,833,159      | 2,804,554      | 58                 |
| 1914 . . . . . | 4,370,239      | 2,256,270      | 51                 |
| 1915 . . . . . | 4,393,178      | 2,147,853      | 49                 |
| 1916 . . . . . | 4,318,201      | 1,929,405      | 45                 |
| 1917 . . . . . | 3,484,218      | 1,361,403      | 39                 |
| 1918 . . . . . | 3,518,735      | 1,125,857      | 32                 |
| 1919 . . . . . | 3,935,681      | 1,581,346      | 40                 |
| 1920 . . . . . | 4,231,951      | 1,627,693      | 38                 |
| 1921 . . . . . | 3,199,330      | 1,421,858      | 44                 |
| 1922 . . . . . | 4,168,257      | 2,037,476      | 49                 |

France is by far the most important market for Welsh anthracite, taking from 60 to 65 per cent of the total exports, and Italy is second, taking about 15 per cent. The remainder goes chiefly to Sweden, Spain, Netherlands, Norway, Denmark, Egypt, and Portugal,

in the order named. These markets and their relative importance in the Welsh anthracite coal trade have not varied greatly in the last 8 to 10 years.

With large measures of first-class anthracite coal at their disposal, and lying convenient for export at an average distance from port of not more than 25 miles, Welsh anthracite coal owners are seeking new markets for their product, both on the Continent, where Welsh anthracite already is widely used, and in other parts of the world. There is at present a plan under way for increasing the consumption of Welsh anthracite in Canada. Also, within recent months, considerable tonnage has been shipped to the United States.—U. S. Commerce Reports.

### SULPHUR AND PYRITES IN THE UNITED STATES, 1922

The output of sulphur in the United States in 1922, according to the Geological Survey, was 1,830,942 long tons, as compared with 1,879,150 long tons in 1921; but the shipments, which were 1,343,624 tons, greatly exceeded those in 1921, which amounted to 954,344 tons. The large stocks previously accumulated by producers were materially increased during 1922.

The total value of the sulphur shipped was greater in 1922 than in 1921, but the value per long ton was less. The value of the sulphur produced or shipped can not be estimated accurately because the only indexes of value available are the market quotations, which show only the selling price at certain times, and as the quantities sold at each price quoted are unknown, the weighted average price can not be calculated.

The imports were so small as to be negligible, but the exports amounted to about 487,969 long tons, compared with 285,762 tons in 1921, an increase of 202,207 tons, or about 71 per cent.

Nearly all the foreign producers of sulphur find themselves unable to compete with American sulphur in most foreign markets, and a great export market for American producers awaits only restoration of good foreign trade conditions.

In 1922, as in other years, Texas and Louisiana produced practically all the sulphur marketed.

The output of pyrites in the United States in 1922 amounted to 169,043 long tons, somewhat more than the output in 1921, which was 157,118 long tons, but the value was considerably less. The imports in 1922 were 269,947 tons, an increase of 53,718 tons over those in 1921, which were 216,229 tons.

Nearly all the pyrite marketed was produced in California and Virginia. The future of the domestic pyrite industry, except at a few places that are very favorably situated, is not promising. Domestic pyrite can not, under normal conditions, compete in markets on the Atlantic seaboard with domestic sulphur or with Spanish pyrite.

The increasing use of carbon black as a filler in the rubber industry has expanded its market considerably in recent years. This should prove of interest to the producers of natural gas in the Canadian west, who can make it cheaply.

The world's oil production for 1922 is estimated at 848 million barrels, or 120 million tons. This is 80 million barrels above all previous records.

# THE MINING DISTRICTS

BY THE JOURNAL'S CORRESPONDENTS.

## NORTHERN ONTARIO

**Cobalt.** — At the new shaft of the Colonial property, a vein was interrupted a few feet from the station in which silver has been found. While the grade is not high, it is encouraging to find silver so close to the shaft, particularly as the vein encountered does not appear to be the main one, to intercept which the shaft was sunk.

On the Violet property, adjoining the Colonial, cross-cutting has been started at 150 feet to cut the old levels in which high-grade ore is known to exist. The last work done on the 600-foot level of the old workings disclosed a new ore-shoot that produced 45,000 ounces in 45 feet of drifting. It is expected that regular production from this property will be commenced before the end of the month.

At the Beaver property, which is under option to the Coniagas, several high-grade shoots have recently been encountered, which add materially to the value of the property. The ore is being broken down into stopes and at present no attempt is being made to sort it. It is expected that the mill will be started in June.

**South Lorrain.** — The Mining Corporation is preparing to sink two new shafts on its South Lorrain property and is installing a larger plant. Development in the district has been very badly hampered by the condition of the road, which is in extremely poor shape. The government undertook to put the road in shape last year, but spent most of the time on the part that least needed it. The Northern Development Branch has promised, however, that action will be taken and that the road will be improved. At the present time it is practically impassable.

The Keeley announces that no dividend is to be paid immediately, as the company desires to conform to the English custom of paying dividends semi-annually. The company proposes to increase the mill capacity from 60 to 125 tons a day and is also making extensive improvements at the mine. Sinking to the 550-foot level is to be started immediately in order to open up the Woods vein and No. 26 vein at that depth. The Keeley is now one of the most important silver producers in the continent and could greatly increase production if it desired to do so.

Mr. Hamilton B. Wills, president of the Keeley, and associates, have purchased the Maidens Silver Mine in the vicinity of the Keeley. The property has produced some ore and is understood to have a certain amount of milling ore developed.

**Porcupine.** — Mr. J. B. Holden, a director of the Hollinger, has issued a statement on behalf of the company in which he says there is absolutely no truth in the report that the control of the mine is passing into the hand of English and South African interests. He also states that no person connected with the Hollinger is either endeavoring to, or desirous of, dising done by the promoters behind the Matachewan posing of control.

The Coniagas is installing a large electrically driven plant at the Newray, in order to permit of development being carried to 1000 feet. A steel head-frame will be erected over the new shaft, which is to be located west of the old workings. Practically no information has been given out by the Coniagas as to the result of developments to date, but the preparations being made indicate that the company is ready to make a large expenditure in order to test thoroughly the possibilities of the property.

At the Vipond the work of putting the mill in shape for operation has been commenced, and it is expected that within a few months milling at the rate of 75 tons a day will be under way. Further development on the new vein on the 400-foot level continues to show satisfactory results.

The Davidson is making preparations to sink a 1000-foot inclined shaft and has purchased a new hoist for it. A site is being cleared for a 500-ton mill, and construction is expected to commence this summer.

At the meeting of the Porcupine Miners' Union, which was held last Sunday and at which it was thought a strike vote might possibly be taken, it was decided to try to confer with the mine managers regarding the Union's request. The meeting was poorly attended, and while there is still a possibility of trouble, it is not expected that it will develop.

**Kirkland.** — Directors of the Lake Shore have declared the regular quarterly dividend of 2%, payable May 15th to shareholders of record May 1st.

Kirkland Lake Proprietary, which is now adequately financed, has acquired controlling interest in the Bush Mine in British Columbia, as well as an interest in the Porcupine field. Developments at the company's property in Kirkland are understood to be encouraging.

Mr. A. D. Miles, representing the English house of John Taylor & Sons, has acquired an option on the Kirkland Townsite property, consisting of 85 acres lying to the south of the Wright-Hargreaves. A new English company will be formed with a £300,000 capitalization, of which the Townsite shareholders get one-third. The sum of £20,000 is to be raised for the purpose of development and for a small payment for the option. It is understood that a shaft will be sunk to a considerable depth with the hope of picking up the extension of the Lake Shore No. 1 vein. The Townsite is one of the last close-in properties to be developed and from its location is favorably thought of.

A public offering of shares is being made by the Kirkland Hudson Bay Company, in which the Hudson Bay Mines of Cobalt has a large interest. The capitalization of the Kirkland Hudson Bay is 2,000,000 shares of \$1.00 par of which 1,523,000 shares have been issued. A shaft is to be sunk immediately to explore the property at depth.

**Matachewan.** — Some very clever advertising is being done by the promoters behind the Matachewan

Canadian Gold Mines Limited, who are offering 600,000 shares of stock at \$1.00 per share, which is the par value. As usual in this class of advertising, hope is held out that the property will be another Hollinger and that an investment of a few thousand shares will bring relief from all financial worries for the future. The property may possess a good deal of merit; but the methods of the promoters are not such as to commend it, and the advertising would carry a good deal more weight if it were supported by the report of an engineer who has no financial interest in the promotion.

**Larder.** — Following the recent annual meeting of the Canadian Associated Goldfields, one of the shareholders who was heavily interested in the earlier company, stated to a Toronto newspaper that he proposed to ask the Crown Attorney to investigate the affairs of the company, particularly as to the original promotion, the deals between the promoters and the company, and the means whereby the hands of the early shareholders have been tied. Prior to the acquisition of the new claim, adjoining the Crown Reserve property, there was a good deal of talk regarding the advisability of an investigation of the affairs of this company by Provincial authorities. Through various reorganizations and the taking in of other properties, the capitalization was raised to \$30,000,000, and stock was sold in this company at quite a high price, based on glowing promises about the profits to be derived from the 10,000-ton mill the company proposed to build, and for which, of course, there was just about as much justification as there was for a capital of \$30,000,000. It is understood that the most promising discovery on the company's properties is on the claim adjoining the Crown Reserve, where a continuation of the Crown Reserve vein has been found and developed.

## NOVA SCOTIA

**Coal on Way to Montreal.** — The opening up of the St. Lawrence, is awaited anxiously by the mine workers of Nova Scotia, just as is the summer sun by the farmer. This year the season is late, and great fields of ice stretching far beyond the vision of the eye lie on the Cape Breton coasts. Through these ice fields large ships find it very difficult to pass. The heavy Arctic ice and the Gulf ice met this year, forming an almost impassable barrier. The colliers bound for Montreal were forced to change their route and pass down through the Straits of Canso. This is something new in the history of Nova Scotia coal transportation; but that the vessels are now on the way to Montreal is the one thing that pleases us.

**Good Production of Coal in Cape Breton.** — The coal output of the Dominion Collieries in Cape Breton for the first four months of the year was 1,466,246 tons, against 833,576 tons for the same period last year. At this rate of increase (and it should be larger during the summer months), the output for the year should exceed that of last year by almost two million tons. Of the amount mined so far, 410,000 tons is still in stock piles. The bulk of the remainder was sold in the New England market. This is the natural market for Nova Scotia coal. It is much closer to the Cape Breton collieries than the Quebec market. There is no closed navigation season, as the ports are always open, and

if it was a market on which Nova Scotia could always rely, it would greatly lessen the amount of coal to be stocked in winter and save the tying up of capital, to cover the wages paid out during two or three months when coal cannot be shipped to Canadian consumers. Other districts of the province show increased outputs, and the coal industry bids fair to close up a large part of the gap between the 1913 and 1922 outputs.

**Wise Workmen.** — The works of the Nova Scotia Iron and Steel Co. at Trenton are having a busy season, and have orders ahead to keep the plant running steadily for some months to come. Realizing the necessity of doing their part in fostering and helping the industry, the steel workers of Trenton have formed shop committees to transact their business and discuss grievances with the Company. Men who take this attitude are prudent, and will no doubt be repaid by steady employment, for the stabilizing of business is the one prime requisite at the present time.

Cape Breton has had its thrills lately in labor circles, and after the great display of Turkey red cotton in Glace Bay streets on May the first, the stocks of W. U. Cotton slumped badly in the market, and he found himself railroaded out of the district and on his way back home. He had given his confederates "some service", and they know it, but that did not save him from the evil day. Although a bold attempt was made to saddle him on the U.M.W. organization, the Locals would have none of it. The day of revolution he so fervently preached in the "Labor Herald" became for him a day of retribution, exacting the penalties of a fickle public who clamored for another editor.

**The Brave Man Runs.** — A Red Editor, Malcolm Bruce of the Workers Party, Toronto, came to Glace Bay, defied the "Red Flag", and publicly prayed for the day to come when its folds would o'erspread the whole earth. He is said to have insulted the Union Jack. Whether this is true or not we cannot say; but the Attorney General of Nova Scotia expressed the desire to meet this latest "Red Missionary", and sent for him to come to Halifax. Bruce, however, unlike a great Scottish namesake, did not relish the honor of falling in freedom's cause, and fled, and though diligent search was made for him, he could not be found. There is no price set on his head, for he isn't worth it; but he has learned that it is not yet quite safe to pray for "Red Flags" in public meetings at Glace Bay. The good citizens of Cape Breton are, to use a slang term, "fed-up" with this Red stuff, and are giving evidence that their patience has reached the limit, and they are going to have no more of it. Even in one of the Locals of the U.M.W. a riot was almost precipitated when one of the Red members began preaching his doctrines too loudly.

The uses of chromium as an alloying element, particularly in steel, are becoming more numerous and more important with remarkable rapidity. The prospective value of deposits of chromium ore is thus enhanced, and it is well worth the attention of prospectors.

The "Mining Journal", London gives warning of a pending scarcity of manganese ore.

## BRITISH COLUMBIA

**Limestone Quarry on Texada Island.** — An extensive belt of limestone, found in the northern part of Texada Island, is being exploited on a large scale by the Pacific Lime Co., which owns approximately 1,000 acres. Their plant is situated at Blubber Bay and the chief quarries are in that section. A contract has been entered into for the shipment of 25,000 tons to the Granby Consolidated Mining and Smelting Co. at Anyox within the next twelve months. A new crushing plant is being installed for the purpose of preparing the material in accordance with contract terms. The company also deals in burnt lime and hydrated limestone, operates its own saw-mill and barrel and stave factory and employs some 150 men.

**Portland Canal.** — Pronounced activity is reported from the Portland Canal District. Camp and mine supplies are being shipped to the Virginia and Taurus Groups, on the Alaskan side of Salmon River, by the Virginia Alaska Co., and Mr. Andrew G. Larsen the managing engineer, has arrived at Stewart to take charge of development operations. Much the same kind of preparation is being made in connection with the property of the Premier Extension Gold Mining Co., of which Malcolm McKenzie, formerly in the employ of the Premier Mining Co., will have supervision. An oil tank of 15,000 gallons capacity, a new compressor, and a large quantity of general supplies, have been delivered at the Indian Mine over the snow.

B. W. W. McDougall has taken hold of the Daly Alaska Mine and new machinery is being shipped to the property. Ridgeway R. Wilson, managing engineer of properties controlled by the Trites, Wilson and Wood interests, has reached the North. Prospects whose development Mr. Wilson will supervise include the Big Missouri, Unicorn and International Groups on the British Columbia side of the boundary and the Stoner Group in Alaska.

**Granby's New Mine.** — H. S. Munro, general manager of the Granby Consolidated Mining & Smelting Co., who recently visited the Outsider Group, Maple Bay, Portland Canal, is quoted as stating that a substantial tonnage of copper bearing ore is likely to be shipped from this point during the summer. Ore bunkers, a wharf, a tramline, and additional camp facilities are among the projected improvements. On the Sunshine Group, also under bond to the Granby Co., a considerable amount of stripping will be done before further underground development is proceeded with.

**Alice Arm.** — The Homestake, Kitsault Glacier, Alice Arm District, is to be opened up further this season. The Homestake Mining Co. proposes driving at least 300 feet of tunnel. The ore-body encountered on No. 1 tunnel will be cross-cut and No. 2 Tunnel will be continued. The Bellevue, on the Illiance River, also is to be developed by the Alice Arm Holding Co. while the War Dance Group on the northeast fork of the Kitsault River, the Horseshoe Group, McGrath Mountain, and the Cariboo Group, Lime Bay, are other properties that will have attention.

**Smithers.** — Since the Henderson Mine, Hudson Mountain, near Smithers, has been opened up and highly satisfactory returns received from the several carloads of ore shipped to the Trail Smelter, there are marked signs of mining activity in this district. A first-class wagon road is to be constructed from Smithers up the mountain to tap the Henderson and the various prospects in that locality. The Provincial Mines De-

partment is undertaking the construction of the trunk road and the mine owners will build branches to their properties. J. F. Duthie, who manages as well as holds a large interest in the Henderson, is making large expenditures on mine plant, which is being shipped and installed at the present time.

The Federal Mining & Smelting Co. are going ahead with the development of their Dome Mountain property in this section. A compressor, drills, boiler, and other equipment is being taken in and the management expects to be in a position shortly to recommend the installation of a concentrator.

**Mineral Exhibit in Spokane.** — The minerals of the Kootenay and Boundary Districts of British Columbia are to be displayed at the forthcoming Annual Convention of the Northwest Mining Assn. at Spokane. The Prospectors' Association of the Interior has been engaged in collecting this exhibit and it is stated that their efforts have been so successful that the Province will be worthily represented. F. A. Starkey of Nelson is in charge of this work and expects, when the time comes, to lead a large body of Canadian mining men to the Spokane conference.

**No Testing Plant this year.** — Mining men of the Kootenays are disappointed because of the announcement that no provision is being made by the Dominion Government for the establishment of an ore-testing-plant in British Columbia. The estimates for the new year, it is stated, will not carry the \$100,000 appropriation required for the installation. Instead there will be a vote of \$5,000 that can be drawn upon by the mine operators of the west for the payment of freight charges on shipments of ore to the testing plant at Ottawa.

**Greenwood Mine Sold.** — The Providence Mine, Greenwood, was auctioned by the sheriff several weeks ago and passed to William Madden, former manager of the mine, for \$2,000, which means that the creditors will receive about 7 cents on the dollar. The property is subject to a bond issue of some \$50,000. It is stated that operations will be resumed in the course of a few months.

**Trail Ore Receipts.** — Ore receipts at the Trail Smelter, Consolidated Mining & Smelting Co. of Canada from April 15 to 21st inclusive totalled 7,428 tons. The shipments in detail follow:

| Mine .. . . .                          | Tons  |
|----------------------------------------|-------|
| Black Rock, Northport, .. . . .        | 107   |
| Company Mines .. . . .                 | 6,548 |
| Knob Hill, Republic, Wn. .. . . .      | 158   |
| Lone Pine, Republic, Wn. .. . . .      | 166   |
| Paradise, Invermere .. . . .           | 92    |
| Rosebery-Surprise, New Denver .. . . . | 54    |
| Silversmith, Sandon .. . . .           | 190   |
| Standard, Silverton .. . . .           | 113   |
| Total .. . . .                         | 7,428 |

**Belmont-Surf Inlet Report.** — The annual report of the Belmont Surf Inlet Mines Ltd., operating on Princess Royal Island, just issued, shows a 100 per cent increase in profits during the year just closed over those of the preceding twelve months. The value of the ore milled increased from \$6.89 to \$8.76 per ton, which explains the generally improved position of the company. 105,971 tons of ore was mined and milled as compared with 134,570 tons in 1921 and the operating

profits were \$112,702.95. A dividend of 2½ per cent was paid, absorbing \$62,500, and \$57,655.03 written off for depreciation. The average metal content of the ore was 0.375 ounces gold and 0.189 ounces silver per ton, and 0.329 per cent copper. The production was 35,014 ounces gold, 17,105 ounces silver, and 697,058 lbs. copper. The ratio of concentration was 11.02 into 1, and recovery of values 89.36 per cent, leaving the loss in milling at 10.64 per cent. Mining costs were \$3.695 per ton and milling 9.2 cents. Flotation royalties were reduced from 8½ cents per ton to less than a cent per ton. Owing to greater underground expense and the more refractory character of the ore, total costs increased 52 cents per ton. Ore reserves are placed at 32,200 tons actual and 68,025 tons possible ore, a reduction of 37,553 tons on the estimates of the previous year. There are good possibilities of a large increase in the ore reserves. The values realized from ore shipments amounted to \$663,265.12. The expenses of mining and milling were \$552,408.

**Yukon Silver Ore.** — It is estimated that some nine thousand tons of high-grade silver ore will be shipped from the Mayo Camp, Yukon Territory, as soon as navigation opens in the waterways of the Yukon and Alaska. Four large steamers and fourteen of the barges available are being prepared for the service. In May, June and July these will be engaged in carrying the ore down the Yukon River to the American Government's new Alaskan Railway, which will take it from Nenana on the Tanana River to the coast terminal at Seward and Anchorage, Alaska, where it will be transferred to ocean vessels on the last "leg" of its journey to the smelters. It is stated that this down-stream haul on Yukon waters has so reduced transportation charges that it will be possible to handle ore of a lower grade than heretofore.

**Proposed Iron and Steel Plant.** — H. J. Landahl, of the Coast Range Steel Co., recently addressed a meeting of business men of Vancouver, urging co-operation and

support in the endeavor he and his associates are making for the establishment in British Columbia of an iron and steel industry. He recited what had been done in England and Eastern Canada in the way of organization, declared that Canadian and foreign concerns now serving the market were hostile, and said that the West should pull as a unit for the enterprise if the early development of its immense resources was desired. Mr. Landahl's project was warmly endorsed and a committee of five was appointed to keep in touch with the company and to tender all possible assistance.

**C. I. M. & M.** — The B. C. Division of the Canadian Institute of Mining & Metallurgy will meet on May 14th in Vancouver to tender a farewell dinner to Mr. Guernsey, the retiring chairman.

**British Empire Exhibition.** — It is assured that British Columbia will be represented at the British Empire Exhibition, to be held next year in London, by a mineral exhibition that will worthily illustrate the resources of the Province, stated the Hon. Wm. Sloan recently. W. D. Dalglish, chief of the Minerals Division, Canadian Government Exhibition Commission, is in Vancouver and called on Mr. Sloan to discuss the business of collecting an exhibit from this province for shipment to the Old Country as a part of the Canadian display.

The work of assembling such an exhibition has been in progress here for months under the supervision of Wm. Fleet Robertson, Provincial Mineralogist. Specimens have been obtained from most of the producing mines of the Province. Many are yet to be secured from the different districts. The work of selection from each of the mineral-bearing sections, having in mind the long productive Kootenays, the riches of the Boundary, the wealth of the historic Cariboo, the phenomenal showings of the Northwest and Northeast, as well as the substantial but comparatively little developed resources of the lower Coast and Vancouver Island, will be continued until there has been gathered a display that will be thoroughly representative.

Mr. Dalglish was promised the complete co-operation of the Provincial Department of Mines in this task. He will spend several days here in conference with local officials. In his opinion the Canadian mineral exhibition will excel that shown at the Panama Pacific Exposition in 1915; in fact it will be the finest that has left this country and in large measure its merit will be due to British Columbia's contribution.

Mr. Sloan states that Canada's building will be on a scale, in point of size, never before undertaken by the Dominion in connection with exhibitions. There has been included already in the main estimates \$500,000, which will be swelled by \$250,000 in the supplementary estimates. Thus there will be three quarters of a million dollars available for the preliminary work in building and otherwise preparing for Canada's representation at the Empire Exposition. Canada's keenest competitor among the Dominions will be Australia but from the plans under consideration the Canadian mineral feature should outstrip all others.

Systematic exploration has disclosed in the Panhandle region of northwestern Texas beds of potash salts that promise to be commercial, both as to grade and as to quantity. It occurs as layers rich in potash salts within thick beds of common salt, lying at depths up to 2000 feet.

#### PURCHASE OF GOLD ORES

The attention of prospectors and others is drawn to the provision in the Mining Act of Ontario authorizing the Department of Mines to purchase parcels of gold ore taken out by prospectors and others in developing or working mining claims. Arrangements have been made by which such parcels of gold ore, whether large or small, will be accepted by the Temiskaming Testing Laboratories at Cobalt, and paid for according to the schedule provided for the purpose. The Laboratories are operated under the auspices of the Department of Mines.

This offers a first class opportunity for testing the value of ores on a large scale, and also of turning ore of good quality into money for carrying on further development work. By special arrangements, on less than carload lots, freight rates on the T. & N. O. Railway are reduced 50 per cent.

The Laboratories are also equipped for working out the best methods of treatment for gold or silver ores of a refractory or unusual character.

Full information as to treatment charges, schedule of payments, etc., can be obtained from the undersigned, or from A. A. Cole, Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

THOS. W. GIBSON,  
Deputy Minister of Mines.

Toronto, 12th March, 1923.

## GREENING'S WIRE CLOTH AND SCREENS

The superiorities that users have come to expect from any article bearing the name Greening results from the highest standards of manufacture plus a long and intimate knowledge of the condition of service under which their products are used.

For more than sixty years the B. Greening Company have kept accurate records of all statistics that effect the wear, service and cost. These statistics are at the disposal of anyone and frequently save purchasers time and money.

## ONTARIO WIND ENGINE & PUMP CO. TORONTO MINING TANKS

"We have used a number of your 6-ft. x 12-ft. and 4-ft. x 12-ft. pine Tanks in our Concentrating Plant. Some of these Tanks have been in use for about four years and have always given perfect satisfaction."

Moose Mountain, Ltd., Sellwood, Ont.

When customers write thus (and we have many such letters in our files) we need say little ourselves regarding Toronto Mining Tanks. All Toronto Tanks are designed and built from the finest Tank materials. Toronto Mining Tanks can be supplied in B. C. Fir, Redwood, Gulf Red Cypress or White Pine. Our Engineering department will gladly furnish estimates and specifications free on request.

## The British Empire Steel Corporation, Limited

by reason of the magnitude of the operations  
of its constituent companies, is able to render  
a wholly unique service to the industrial or-  
ganizations of the world—and of Canada in  
particular.

The vast scope of these operations necessitates  
the maintenance of the highest possible stan-  
dards of efficiency and economy, which,  
naturally, reacts to the benefit of our cus-  
tomers.

*A Typical Dodge Job.*

The illustration above is of a group of Cast Iron Cone Pulleys made by us for a large Paper Mill in Quebec. This job is one of many fine examples of work done in our Foundry and Engineering Shops.

*Thirty-Seven years  
Foundry and Engineering Experience  
At your Service*

The vast number of patterns, accumulated over a period of years, enables us quickly to manufacture Single Belt, Double Belt or Triple Belt Cast Iron Pulleys.

All Dodge Pulleys are designed and constructed to withstand those reasonable strains under which they can properly be expected to operate.

Setscrews are regarded as an adequate holding for Single Belt Pulleys. When such Pulleys are keyseated, an extra charge is made for keyseating. Double and Triple Belt Pulleys are provided with key-

ways, and with two setscrews over the keyways. This is standard practice, and no extra charge is made. Keys are never furnished with Pulleys unless specifically ordered.

When ordering Pulleys, please specify exactly.

- (1) Single or Double Belt Pulleys,
- (2) Solid or Split Construction,
- (3) Crown or Straight Face,
- (4) Setscrews only, or Keyseated and Setscrews,
- (5) Any special conditions of service.

We can give prompt and reliable service on immediate orders.

# Minerals

PROVINCE OF ONTARIO

DEPARTMENT OF MINES

HON. H. MILLS, Minister of Mines

## Mineral Areas.

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favorable for the occurrence of minerals, 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver mines of Cobalt occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

## Economic Minerals.

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario:—actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluor-spar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, Portland cement, brick and tile, meet every demand.

## Mineral Production.

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1921 to be worth \$48,128,387, of which the metallic production was \$27,574,202.

The following figures show the rapid growth of Ontario's mineral industry by five-year periods since 1891:

| Year.      | Value.      | Year.      | Value.       |
|------------|-------------|------------|--------------|
| 1891 ..... | \$4,705,672 | 1906 ..... | \$22,388,383 |
| 1896 ..... | 5,235,003   | 1911 ..... | 41,976,797   |
| 1901 ..... | 11,831,086  | 1916 ..... | 65,303,822   |

## Dividends.

Dividends and bonuses paid to the end of 1921 amounted to \$23,140,734 for gold mining companies, and \$84,388,185 for silver mining companies or a total of \$107,528,919.

## Mining Regulations.

A miner's license costs \$5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of \$2.50 or \$3.00 per acre, depending on location in unsurveyed or surveyed territory.

## Assay Office.

The Provincial Assay Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

## Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward; and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

## Publications.

# Adding Impetus To The Development Of Mining

The development of Canada's enormous natural resources will affect her whole future. Her vast mineral wealth, as yet practically untouched, is to-day attracting world-wide interest from far-seeing investors.

It is appropriate that the Imperial Bank, whose policy has ever been to concentrate exclusively on Canadian affairs, should be powerfully furthering that interest. This Bank, by placing branches at strategic points throughout the mining districts, has materially aided the whole industry.

Those who contemplate becoming connected in any capacity with mining would be well advised to take advantage of this Bank's facilities.

## IMPERIAL BANK OF CANADA

Peleg Howland, President.

A. E. Phipps, General Manager.

## HOLMAN AIR COMPRESSORS

200 cu. ft. compressor

THE HOLMAN NEW STANDARD AIR COMPRESSORS fitted with feather plate valves present are exceptionally quiet smooth running efficient machines. The rated capacities refer to actual delivery not displacement. They can be arranged for belt or electric drive and are also made in portable units.

### EFFECTIVE PUBLICITY NEEDED

The reputed finds of placer gold in Labrador have attracted official attention. We reproduce today on another page the pronouncement of the Geological Survey, Ottawa. It is a straightforward recital of the known facts and logical deductions, with the inevitable conclusion that the "finds" are most likely a fraud.

The publication of this report by the Geological Survey might be considered timely if it were not four months too late. Most of the damage has been done. The public's money has been gathered in, the good name of various reputable men of science and explorers has been misused by the culprits, and Labrador, a genuine land of promise for the prospector, has been made a laughing-stock on two continents. This might have been prevented. All the information quoted in the Survey's report was available in January, when the *Canadian Mining Journal* came to exactly the same conclusion from the same data as the Survey has reached now, four months later.

One cannot doubt the intention of the Geological Survey to serve the mining industry and the public by every means at its command. It has an enviable reputation for sound judgment and conservative conclusions which is a valuable asset to itself and to the country and must not be impaired. Nevertheless we are of the opinion that this Labrador incident illustrates a grave defect in the organization, not only of the Geological Survey but of its other half, the Mines Branch. We alluded to this defect a few weeks ago. The Department of Mines in Ottawa has no officer whose duty it is actively and consistently to make and retain an effective contact with the public. The Department needs a publicity officer.

As it is at present constituted, the Geological Survey can be expected to deal with a public scandal like this Labrador affair only when its attention has been drawn forcibly to it by the march of events, and some action forced upon it. Even then, it falls to the lot of some official fully occupied in another line of work to deal with the case. In this instance, Labrador Gold-fields, Limited, was actually made the subject of questions in the House of Commons on May 14th by Mr. Gauvreau, the questions being answered by Hon. Mr. Copp. Fortunately, the Survey's report antedated these questions by a few, though very few, days.

The branches of the Department of Mines can do a very valuable work of leadership, in addition to what

they are already doing, if they are allowed the opportunity. At the present juncture, when capital in large amounts is available for mineral development and when a host of get-rich-quick gentry infest our land in the hope of diverting part of this money into their own pockets, it is surely worth while to provide for this special need. The proper man acting as liaison officer between the technical staffs of the Department of Mines and the public will certainly save many times his salary, and might conceivably save millions of dollars annually.

### NEW LIGHT ON AN OLD GOLD DISTRICT

It appears at present as if the Lake of the Woods gold region of northwestern Ontario had re-commenced a useful existence. For quarter of a century it has remained for the most part dormant, having been effectually put to sleep by an over-dose of opiate in the form of stock-jobbing and mismanagement. Authentic records of "showings" uncovered at that time demonstrate the existence of prospects, still in the main undeveloped, such as would stimulate a "rush" of both prospectors and capital were they discovered anew today.

In spite of the prevalence of mismanagement, one property, the Sultana, was worked consistently and made money for its owner, and the reason for its closing down in the midst of a useful career has remained somewhat of a mystery. The vein outcropped near the shore of a peninsula and an outsider staked the water rights. The opinion current among the "old timers" in Kenora is that the vein dipped under the lake, off the Sultana property, and that rather than deal with the holder of the water rights, the owner preferred to close down his mine.

For several months the Mikado mine has been under examination and active development by Colonel H. A. C. Machin, and it is reported that the result of this work has been distinctly encouraging. It is a bold stroke to undertake thus the rehabilitation of an abandoned and discredited mine, made malodorous by former financial manipulations, and Colonel Machin's efforts deserve a full measure of success. If the result of his work continues to be as satisfactory as it has been to date, we may expect to see operations at the Mikado firmly established from now on. In this case there will be a general revival of interest in the district.

The geological mapping of the Lake of the Woods district was done in what has been called shrewdly "the phrenatic era" of geology; rocks were classified according to the colour their outcrops presented, and it was quite unnecessary for the geologist to leave his canoe. Nevertheless the old maps are useful in delimiting the areas of granite and of the older basic rocks, and the prospector of today need not waste time on useless exploration in areas of the former.

Some casual observations on Lake of the Woods a year ago by one familiar with the rocks of the Porcupine and Kirkland districts disclosed some interesting features, not yet officially recorded. This observer found distinct evidences of acidic intrusions, presumably of Algonian age, among the older granitic rocks. He also observed on one of the islands where a new showing of gold had been uncovered an intrusion of porphyry and the rusty weathering carbonate rock typical of the established gold areas. A new study of the area in the light of present-day geological knowledge might well show this area to be the geological counterpart of that six hundred miles to the east, on the other side of the province.

Last autumn a spectacular find of gold was made within the town limits of Kenora, in an excavation being made for a cellar. Subsequent examination showed it to be only an isolated pocket; but what there was of it was amazingly rich. This find caused hardly a ripple of excitement among the residents of Kenora. They have become so "fed up" with disappointment and are so accustomed to hope deferred that what would have set fire to the imagination of the ordinary community and caused a wide-spread search hardly caused them a thought. Still, a handful of the "old-timers" continue to prospect in a desultory way, in spite of the present difficulty of obtaining capital for use there.

The present indications are that within the next few years there will be a general revival of interest in the old gold camps of northwestern Ontario and that then, for the first time, they will have the thorough examination and honest development they deserve.

### THE HUNDRED MILES OF GOLD BELT

Last month Dr. H. C. Cooke, of the Geological Survey, did the prospectors of Ontario and Quebec a notable service by providing for their use, through the pages of the *Canadian Mining Journal*, his description of the new Quebec gold field, including practical and explicit directions for effective exploration and prospecting. He has now extended this service by preparing an article on the eastward extension of this field, which we publish in this issue.

The prospective gold belt of northwestern Quebec is over one hundred miles in length. Only a small part of it, at the western end, has as yet received any

significant amount of attention from prospectors, and to that section will be attracted the larger part of those interested in the field. The possibilities of the eastern part have been merely indicated by the slight amount of work done there up to the present; in fact the only available geological map of that part is, to a large extent, blank, due to no examination having been made away from the principal water courses.

The wise prospector, if he has not already obtained a holding in or about the "rush" area, will keep as far away from the crowd as he can. There is plenty of room. In our issue of May 11th, our Quebec correspondent described effectively the various travel routes available for reaching the gold belt. From Nottaway, Amos and Villemontel on the Canadian National Railways water routes extend southward into the promising areas. From Amos access to the eastern end of the belt is particularly easy, travel by motor boat being practicable for most of the distance. Lake de Montigny, on this route, has been already the scene of prospecting for gold, and a recent newspaper description of the forthcoming visit of a British peer, interested in a property there as well as in the "adjoining" Hattie and Hollinger mines, has cast a new light on Canadian geography and methods of exploration.

Dr. Cooke's article is admirably explicit in its findings and suggestions, and will well repay careful study by those interested in the further and extended exploration of the new gold field.

### EMPIRE DAY

There is much talk these days about the independence of various parts of the British Empire. The creation of the Irish Free State, the granting of a measure of self-rule to the three hundred millions in India, the sovereign independence of Egypt (which the Egyptians are already commencing to regret), and the now famous (or notorious) fish treaty between the United States and Canada mark the tide that ebbs and flows in the sea of political administration, always with a final tendency toward local autonomy and responsible government. Amidst all this talk about independence, one hears seldom of inter-dependence; yet mutual dependence is the solid rock upon which the British Empire is founded. Sentiment, and even at times sentimentality, may play their part in forging the bonds that make the Empire a unit; but self-interest and a common benefit are the principal and the most lasting means of ensuring that our heterogeneous and polyglot Empire shall endure.

Empire Day will always be for those of the older generation the day of the great Queen. In her honour we burned our fingers, frightened the horses, startled our young sisters with strange concoctions of gunpowder and coloured fire, and depleted first our own pockets and then those of our male parents, if they also were infected with the enthusiasm of the

day. However, the current inspiration for thought as well as for enthusiasm is now the Empire that reached its present position of influence and power during the Victorian age. It is to the maintenance of this honourable position on a sound footing that we must direct our thoughts, not only on the twenty-fourth of May, but many times throughout the year.

What does our position within the Empire mean to us Canadians? This question will bring a great variety of answers. Few doubt the fact that "united we stand; divided we fall." As part of the Imperial unit we are free from many of the problems that vex small nations, and on the other hand suffer little from our nearest neighbor, and the balance is decidedly dominions, since we can modify our relations with them at will. The increasing importance accorded to Imperial preference in tariff schedules marks a growing appreciation of this tangible evidence of common interest.

The Canadian mineral industry is as yet comparatively little affected by inter-Imperial trade. Most of our interchange of mineral products is still with our nearest neighbor, and the balance is decidedly against us, principally on account of our imports of coal and iron. Empire Day might well be occupied by those involved in our mineral industry in a study of how to shift part of this account to British books. A good commencement has been made in the case of coal. A firm in Montreal advertises for sale Welsh anthracite, "not semi-anthracite", for domestic use. This inaugurates, we hope, a gradual capture by this unsurpassed domestic fuel of the market within range of Montreal. Coal is one of the few mineral products that can be exported from British mines or quarries. There are numerous possibilities for return cargoes of mineral products from Canada for the colliers from Wales. The thought concentrated on the problem on Empire Day may help to disclose some of these.

#### AN INTER-PROVINCIAL CUSTOMS DUTY EXISTS

An instance of official neglect or maladministration in Ottawa is disclosed in the correspondence and other information we print today relative to shipments via the Panama Canal. Shippers and consumers both in the east and in the west of Canada are suffering from a restraint of inter-provincial trade via this route. It is stated that placing a Canadian customs officer in New York to supervise such shipments where they enter United States territory would right this anomalous situation, and would ensure the Customs Department against fraudulent declarations designed to circumvent the customs regulations. The few instances cited show that an important amount of inter-provincial trade is being hampered, and indeed prevented, by this unwarranted imposition of import duties. The case deserves the serious consideration of the authorities in Ottawa.

The Montreal branch of the Engineering Institute of Canada has now launched what promises to be an unusually useful propaganda. Last winter, its members interested themselves actively in the fuel question, and when the Canadian Institute of Mining and Metallurgy undertook to investigate the sources of fuel in Canada, they decided to look into the question of its use. Recently they issued their first report, describing the various domestic fuels available in the Montreal district, their comparative values, and their estimated cost. Some sound general directions for the use of fuel are included. Welsh anthracite at \$17.00 per ton gives the best value, with an annual cost of \$24.00 per 100 square feet of water radiator surface. American anthracite at \$16.25 per ton gives the least value, at \$32.50 per 100 square feet.

#### A NOVEL CLAMP FOR SHEET METAL

A simple but effective device for clamping the edges of thin sheet metal can be made from a short length of light tubing and a collar to fit. The accompanying photo, showing the clamp applied to the work, illustrates how it is used to aid in cutting off strips of this material.

Cutting duplicate strips of sheet metal by hand methods generally necessitates the use of some device enabling the work to be performed quickly.

Usually the first piece cut is used as a gauge for cutting the others. In such cases the clamp shown is useful as it is made to clamp the work and line up the edges at the same time. This is accomplished by sawing a slot in the tube and collar to take the work, and enlarging the diameter of the tube somewhere near the centre by punch or chisel marks, these raised portions of the metal being afterwards filed so that when the collar is pushed into this part of the tube the latter is squeezed together and thereby made to tighten on the sheets in the slot.

The tube used should be as light as possible, to afford easy gripping. The collar can be of any size and width so long as it fits the tube.

In use, the two pieces of sheet metal are lined up approximately at the edges and the device shown is slipped on until the edges of the metal strike the back side of the tube bore. When this takes place the collar is slid sideways onto the enlarged part to contract the tube, and close the slot, and so pinches and holds fast the two sheets in the slot.

# Exploration for Gold in Northern Quebec\*

BY H. C. COOKE.

The *Canadian Mining Journal* of April 13th contained a short paper describing briefly the results of our last year's field work in the Opasatica area of northern Quebec, particularly those results bearing on the occurrence of gold in the area, together with a number of suggestions to prospectors as to the best way of prosecuting the search for new deposits. The editor of the *Journal* has intimated that a supplementary paper is desirable, summarizing the facts and the possibilities of the whole district in a general way.

## Reports on The District

The accompanying sketch map shows the general distribution of the rock formations of the district. It has been compiled from the published maps of the Geological Survey and the Department of Mines, Quebec. The area from the Ontario-Quebec boundary east to Kewagama lake was explored by Dr. M. E. Wilson who also studied the area around Bell river; his results are to be found in Geological Survey Memoir 39, entitled, "The Kewagama Lake Map Area, Quebec," and in a paper entitled "A Geological Reconnaissance from Lake Kipawa via Grand Lake Victoria to Kanikwanika Island, Bell River, Quebec", in the Summary Report of the Geological Survey for 1912. The district between Kewagama lake and Bell river has been examined by Dr. J. A. Bancroft, whose observations are published in the Reports on Mining Operations in the Province of Quebec for 1911 and 1912, published by the Quebec Department of Colonization, Mines and Fisheries. Both of these writers did reconnaissance work only, examining and mapping the outcrops on the shores of the principal waterways and making only an occasional trip inland, here and there, to determine the nature of some prominent hill, to examine a mining claim or to map the rocks for a few miles along some township line.

## Extent of Pontiac Series

The information gained by Bancroft and Wilson indicates that the belt of schistose sediments, named the Pontiac series by Wilson, stretches in an unbroken belt some ten miles in width from near the inter-provincial boundary to the eastern boundary of Marrias township, a distance of approximately 100 miles. At the eastern end of the belt there appears to have been a sharp anticlinal cross folding, so that the sediments end suddenly against the underlying Keewatin greenstones. The greenstones outcrop over an east-west distance of at least six miles, around Christopherson lake, one of the headwaters of the Bell river, and east of them the Pontiac sediments appear once more around Matchimanito and Garden Island lakes for a distance of some 12 miles. They are then finally cut off by the northward extension of the great batholithic intrusion of granite.

In Opasatica area the bulk of the sedimentary rocks mapped as Pontiac series have been proved by our

work of last year to be identical with the Temiskaming series of Kirkland Lake. If the same condition held for the whole length of the belt, this paper would be largely unnecessary, as the description of the geology of Opasatica area, in the issue of April 13th, would apply also to the remainder of the belt to the east. This is not, however, the case. Our work last year showed pretty conclusively that the Pontiac series is made up of two sedimentary series of widely different ages. The older is composed of blackish, fine-grained, well-bedded slaty rocks that have been deposited without any marked break directly on the surface of the Keewatin lava flows. They have therefore been included in the Keewatin series of rocks under the name of bedded tuffs. In the eastern part of the Opasatica area the bedded tuffs, which lie on edge like all the older rocks, outcrop over a width of about half a mile from north to south. South of them lies the great body of metamorphosed conglomerates and graywackes termed the Temiskaming series which overlies the Keewatin rocks unconformably.

## Extent of Temiskaming Series

Lacking opportunity to carry on detailed work, however, the earlier explorers grouped together all the sediments, the bedded tuffs and the Temiskaming series, in the Pontiac series. It is consequently not known what proportion of the Pontiac belt of sediments to the east of Opasatica area consists of Temiskaming series, and what is bedded tuff. Bancroft reports occurrences of the schistose conglomerate of the series as far as the eastern border of Bousquet township, so that the bulk of the Pontiac is probably Temiskaming series for 25 miles east of Opasatica map area. In the next 50 miles, however, no conglomerate has been reported and all that is positively known is that much of the Pontiac series at least consists of the bedded tuffs. A little conglomerate is reported by Wilson as occurring on Garden Island lake, near the extreme eastern end of belt, indicating that the conglomerate is probably continuous throughout the whole belt, although perhaps so much thinner than in the west that it happens to be drift-covered along the watercourses. Probably, therefore, the southern part of the band of Pontiac series is Temiskaming series throughout, the northern part of bedded tuffs, from Bousquet township to Marrias township; but the actual width of each formation is as yet unknown.

## Value of Tuff For Prospecting

One can only speculate yet whether the areas of bedded tuff will repay prospecting. It may be presumed that, since the tuffs are bedded, the intrusive gold-bearing porphyries would tend to form large sills rather than small dikes in them; on the other hand, they may be so difficult to fracture across the bedding that porphyry masses may have not entered them at all, or to a very slight extent. The tuffs are comparatively soft, so that a shear zone in it would almost certainly be well defined; on the other hand such soft

\* Published by permission of the Director, Geological Survey of Canada.

rocks yield so readily under shearing stresses that great widths of sheared material may be expected in many instances, and this, as indicated in the previous paper, is usually unfavorable for the formation of a paying ore-body. Since the tuff is soft, veins running into it may be expected to break up into branching networks of small veinlets, or to form a succession of short lenses, very unfavorable for mining purposes; but the fine-grained tuffs are also readily replaced by mineral-bearing solutions, so that a comparatively small vein may be bordered by a sufficient width of replaced and mineralized rock to become a paying proposition.

The tuffs, therefore, which form a considerable part of the Pontiac series east of Bousquet township, are most or less an unknown quantity so far as their prospecting possibilities are concerned. They present both favorable and unfavorable characteristics, and only thorough prospecting, resulting in the discovery or non-discovery of ore deposits, will show finally which characteristics have been the most influential, while more geological work is required to delimit the boundaries of the areas of tuff.

#### Hints to Prospectors

The known facts of the geology of this district, so far as they relate to prospecting, may be briefly summed up therefore as follows.

The band of sedimentary rocks known as the Pontiac series extends easterly from the interprovincial boundary for 120 miles, with a break 6 or 8 miles wide around Christopherson lake, a headwater of the Bell river.

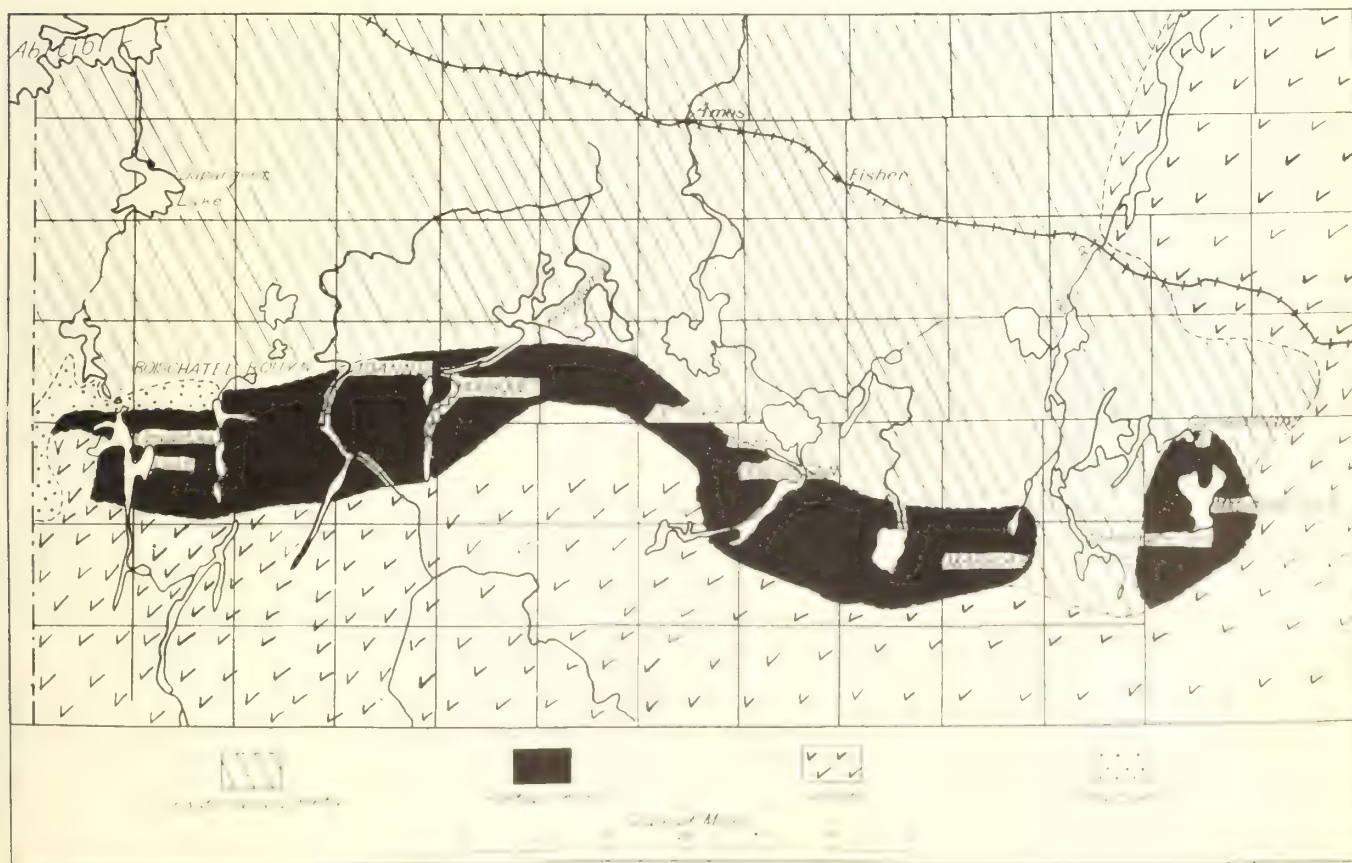

Gold discoveries of probable value have been made in the Keewatin series near the Keewatin-Pontiac

boundary in three localities; near the western boundary of Boischatel township, in the northeast corner of Rouyn township, and in the northern part of Dubuison township. In each of the two latter areas there have been several discoveries.

Throughout Opasatica area and for 25 miles further east, as far at least as the eastern boundary of Bousquet township, the bulk of the Pontiac series consists of the Temiskaming series, and prospecting in the sediments should be confined mainly to the belt of conglomerate about a mile in width along the northern edge. East of Bousquet township a larger proportion of the belt of sediments appears to consist of the Keewatin bedded tuffs, and only prospecting can show whether ore-deposits are likely to be found in them or not.

The occurrence of gold in the Keewatin lavas at such widely separated points suggested strongly, however, that prospecting might be carried on with profitable results throughout the whole belt of Keewatin rocks bordering the Pontiac sediments. All the discoveries so far, it will be noted, are on or close to easily travelled water-courses. It is highly improbable that these are all the deposits in the region; on the contrary, the discovery of no less than three gold-bearing localities, when there are only some 8 or 10 navigable watercourses crossing the belt, strongly suggests the advisability of prospecting the whole belt intensively. There are large areas as yet entirely unexplored between the navigable streams, in which the chances of finding gold are equally as good as in the much-staked Rouyn area.

The prospector entering these areas must be prepared, however, to encounter considerable difficulty.

Sketch Map of the Quebec Gold Belt, indicating the Principal Geological Features and the Main Canoe Routes

It is most discouraging to traverse miles of clay land, and find only a few small and widely scattered outcrops of rock, when the ground is covered with a growth so dense that with the utmost exertion one may scarcely make a mile an hour. Yet this difficulty is what the prospector in this area must expect to meet and overcome, if the area is to be thoroughly examined; it has, indeed, been a main cause in the past for the failure of further prospecting after promising discoveries had been made.

#### A Northern Gold Belt?

The apparent connection that seems to exist between the localities where gold has been found and the general east west structure of the country, suggests another possibility to be investigated by prospectors at some future time. If there really is any connection between structure and gold deposition, then an east-west line drawn through the Porcupine district and projected eastward may prove to be another belt along which gold deposits may be expected to occur. It is interesting to observe that the Lightning river discoveries are approximately on this line. Such a line, projected into Quebec, passes along the north side of Duparquet lake and crosses the National Transcontinental Railway between Amos and Fisher. Much of this district is very heavily covered with clay, but it might prove profitable to prospectors to examine the hilly parts at some time in the future for possible occurrences of gold.

### INSTITUTE MEMBERSHIP

#### Address by Thomas Graham to the B. C. Division C. I. M. and M.

The annual business meeting of the British Columbia division of the Canadian Institute of Mining and Metallurgy was held in Vancouver on May 14th. In addressing the meeting after his election to the chairmanship for the ensuing year, Mr. Thomas Graham said:

In accepting at your hands the office of chairman for the coming year, I desire to express my deep appreciation of the honour you have conferred upon me. While sensible of my own limitations, I shall to the best of my ability endeavour, during my term of office, to advance and promote the best interests of the Institute and its members.

First, permit me to pay tribute to the retiring Chairman and his executive officers. Their untiring efforts during the year have done much to advance the welfare of the Division. Particularly are they to be complimented and congratulated upon the success that attended the Western General Meeting held in this city last fall.

I cannot leave this subject without making reference to the work of our Secretary-Treasurer, Mr. H. Mortimer Lamb. The Division is to be congratulated on having in this important position a man who is so self-sacrificing in time and energy as Mr. Lamb. His able report submitted today gives much food for thought in connection with the future activities of the Division, and it is to be hoped that more local branches can be established through the Province, as they undoubtedly do much to maintain interest in Institute matters. I feel that Mr. Lamb's work as Secretary-Treasurer has been wholly responsible for the renewed activity shown during the past two years in Institute matters in the British Columbia Division.

The subject of Institute policy has been much to the front throughout the past year, and judging from the diversity of opinion among members and the difficulties

in arriving at a fixed policy, it would appear as if there were other complex problems in the world besides those we have often heard so ably treated at meetings of this Institute by Professor Thompson.

The question as to whether or not additional numbers in membership will be a cure for all the ills that at present seem epidemic in the Institute threatens to be a live subject for discussion for some time to come. There is a well defined line drawn upon the subject, and one that it is to be hoped will be approached with that tolerant spirit towards the other fellow's view point that should characterize all our discussions. The various views advanced are well known to you all, and in giving these some thought I am led to think that both within and without the Institute there are many who do not quite grasp the full significance of membership and what it implies.

Most of us expect too much from the Institute without any effort to put anything into it in return. It is an honour to be a member of the Institute, and being honoured in enrollment in its membership, the Institute has a right to expect something from the member in return. The Institute can only be a responsible body insofar as it represents the responsible thought of its members. The Institute exists for this purpose. It is the inspiration of our efforts that holds us together, the knowledge that we are, through responsible thought, building up an influence for good. We want all men of responsible thought, who may and can add their quota to the sum of our experience, to join us, and such men with the interests of the mining industry at heart should feel it their duty to do so, and we welcome them to our ranks, so that the Institute may fulfil the great work that it can perform for the mining and metallurgical industry of Canada.

There may possibly be temporary set-backs to the development of the mining and allied interests in this country, but they can only be temporary. Industrial development of our country is so largely dependent on mining that we cannot hope to obtain and maintain the progress awaiting us if we neglect the mining industries. Therefore, I believe we have reason to look hopefully forward to a period of mining development throughout the Dominion, and an active Institute such as ours should be prepared to play a prominent part in guiding and directing that mining development along lines calculated to bring the greatest possible good to our Province, our Dominion and the Empire.

### MONEL METAL FOR SAFETY LAMP GAUZE

A new and important use has been determined for Monel metal. A report of the Bureau of Mines, Washington (Serial Number 2468) gives the result of an exhaustive test of Monel metal gauze in safety lamps for use in coal mines, in comparison with steel gauze, and the conclusions are as follows:

"Monel metal is a very satisfactory material for flame lamp gauzes. Monel metal gauzes provide as great a degree of safety in gaseous and coal dust laden mixtures as do steel gauzes, and in addition they do not corrode perceptibly in humid atmospheres.

"Monel metal gauzes maintained their shape and stiffness under the greatest heat to which they were submitted in gaseous mixtures equally as well as steel gauzes did; this together with the fact that they do not corrode perceptibly in humid atmospheres should assure a much longer life for Monel metal gauzes.

"It is believed that the use of Monel metal gauzes in flame safety lamps would be a step toward greater safety and that their use should be encouraged."

# Customs Duty Imposed on Inter-Provincial Trade

ANOMALOUS RULINGS IN OTTAWA INJURE  
CANADIAN PRODUCERS IN BRITISH COLUMBIA  
AND NOVA SCOTIA

(Specially Written for the Canadian Mining Journal.)

The statements appearing in the Eastern Press, relative to the collection of duty on Canadian goods by Dominion customs officials, if such goods are shipped, whether in bond or otherwise, via New York through the Panama Canal, are founded on fact. Although western merchants, through the Boards of Trade and strongly supported by newspapers, are making a determined fight to have a Canadian customs officer placed at New York in order that this restriction of inter-provincial trade by the water route may be removed, there is as yet no intimation that the effort will be successful.

Hon. John Oliver, Premier of British Columbia, first turned the limelight on this state of affairs when, in the course of addresses advocating an equalization of freight rates as applied to this Province, he declared that duty had been collected on steel rails shipped from Eastern Canada via New York to Canada on the Pacific Coast. He pronounced this an injustice, said that it was an unwarranted interference with the free interchange of trade by cheaper transportation channel between two parts of Canada, and asserted that it was contrary to the intent of the framers of the British North America Act.

Not to allow the matter to rest with a mere declaration of the fact, Premier Oliver addressed a protest to the Rt. Hon. W. L. Mackenzie King, Premier of Canada, and from him received the following reply:

"Customs Department has arranged for refund of customs duty in case of steel rails referred to in your telegram April twenty-sixth and has in course of preparation regulations respecting goods shipped from one part of Canada to another which it is hoped will satisfactorily meet the other matters to which your wire directs attention."

## Premier Mine Forced to Buy American Goods

It is stated on good authority that the Premier Gold Mining Company proposed purchasing from a Canadian firm at Owen Sound twenty tons of grinding balls, but after finding that they would have to ship all-rail or else ship via New York and the Panama Canal and pay Canadian duty on Canadian goods, they found it cheaper to buy American goods in the United States and pay the duty.

Another concrete case quoted is that in which the Gosse-Millerd Salmon Co., of Vancouver, is the principal. This company addressed an inquiry to the Minister of Customs regarding the status of a shipment of salmon from this province via the Panama Canal and New York to Eastern Canada as to duty charges and received the following reply:

"Under present regulations and conditions canned salmon shipped from British Columbia to Halifax via Panama Canal and New York would not be admitted to Halifax without payment of duty."

A Vancouver newspaper, "The Sun", pressed this matter by telegraphing the Hon. Jacques Bureau, Minister of Customs, Ottawa, in the following terms:

"Referring to your wire Gosse-Millerd stating that

duty would be charged on salmon shipped to Halifax via Panama Canal, please refer section 121, British North America Act reading, 'All articles of growth, product or manufacture of any one of the provinces shall from and after the Union be admitted free of duty into each of the provinces.' With this before you, will you as responsible Minister of the Crown and member of the Liberal party state what your future policy will be with regard to this matter? Kindly wire today."

To this the following reply was received:

Ottawa, April 27, 1923.

Vancouver Sun,

Vancouver, B. C.

"In absence Minister would state that section 121 British North America Act held to refer to movement of goods within Canadian territory and not to shipment via foreign territory."

"Wm. Ide

Private Secretary"

## Customs Officer in New York Advocated

The present situation as to the shipment of salmon to Eastern Canada is set out in the appended communication, dated May 9th last, from W. D. Burdis, secretary of the B. C. Cannery Association.

"In reply to your inquiry respecting the disability placed upon B. C. canned salmon shipped to Eastern Canada via the Panama Canal, by reason of the duty charged on such goods, I assure you such is the case, with the result that, so far as I can learn, no canned salmon has been shipped by that route.

"Had such a regulation not been in effect, sellers here could have done considerable business in Eastern Canada, in canned salmon and other lines, but the regulation effectively debarred our people from availing themselves of the cheaper rates quoted via Panama, viz. 60 cents per 100 lbs. vs. \$1.30 overland by rail.

"I have this morning received a circular letter from Dingwall Cotts & Co., containing a copy of a communication dated May 1st, 1923, that the company has just received from the Department of Customs in Ottawa, stating that goods shipped on a British vessel from Montreal to Vancouver, not landed or transhipped at New York, via the Panama Canal will be admitted here free of duty, but as you will see the reply was in respect to a vessel, the 'Margaret Coughlan', with a full cargo aboard, and does not indicate the position in respect to parcels of goods shipped from Vancouver to Eastern points. Dingwall Cotts & Co. at my request, are writing their agents to ascertain from the Department, whether goods from here will be similarly favoured, say in Montreal.

"I enclose you a cutting from the Sun of April 20th., 1923, which shows the case cited by Gosse-Millerd, Ltd. whereby they lost a sale of goods to a Halifax firm, on account of duty being chargeable on shipments made via Panama.

"I understand the matter is being seriously investigated by the Minister of Customs, who in today's World is reported to have stated a decision will be

dominated and shortly which he expects will be satisfied.

Nothing but the right to ship Canadian-made goods either way in hand, by any vessel via Panama to points in either Eastern or Western Canada, free of duty, will fill the requirements, or better still, the appointment of a Canadian Customs Officer in New York, to deal exactly in the same manner that a United States Customs officer does in Vancouver with shipments of goods entering this port. The cost of the latter officer here, about \$4,800 a year, is paid by the C.P.R. to facilitate shipments over their road of American goods, so the cost of an office in New York would not be a serious item of expense for so great a benefit to Canadian inter-provincial trade."

Hon. Jacques Bureau, Minister of Customs, is quoted in the West as being far from enthusiastic over the proposal that a customs officer be appointed at New York. It is said that he is inclined to refuse the request, justifying his position by the contention that traffic would be diverted towards the United States and that all the Canadian railroads would get out of it would be the haul from the point of departure to the boundary. The whole of the railway haul to the sea and the whole of the ocean freight would go, it is argued, to the United States.

#### Use of Nova Scotia Steel in B. C. is Prevented.

A. B. Weekes of the Canadian North West Steel Company, sets out British Columbia's position as follows:

"We have to buy our iron and steel in England because we can get it delivered here more cheaply than if we bought it from the Dominion Steel Co. of Nova Scotia.

"We cannot afford to pay the rail haul from Sydney to Vancouver and we are not allowed to ship by water through the Panama Canal. If we do try this, when the goods arrive here they are considered to have originated in the United States and we have to pay the full duty. By bringing the goods from England the transportation costs are little greater than from Halifax and the duty is much less.

"The actual difference between the duty we pay on material purchased in England and what we should have to pay if we purchased in Nova Scotia and shipped by the Panama Canal is the difference between \$2 and \$3 on low duty goods and between \$4.25 and \$7 on high duty goods.

"It is of no use for us to tell the customs officer here at this port that we purchased the stuff in Nova Scotia. They say that the ship called at New York or some other American port and they don't know what may have happened there. Maybe the goods purchased at Halifax were taken off and other goods made in Pittsburg were substituted. They have no knowledge.

"That is why the Canadian Government is being so insistently asked to put a customs office at least at the port of New York, the chief transshipping centre. Such an officer could supervise the transshipping activities and certify to the identity of the merchandise.

"The suggestion that the Government refuses to take this step in order to compel us to use the Canadian railways instead of the American ships does not work out, for we do not buy in Nova Scotia. We cannot afford to do so. Our goods are not handled on one mile of Canadian railway. Not only do the railways lose the short haul from Sydney to Halifax, in our case for instance, but the Canadian steel producer loses the British Columbia market to the British producer."

#### NEW REPORT ON SYDNEY COAL AREA

A recent and timely publication of the Geological Survey, Ottawa, is Memoir 133. "The Southern Part of the Sydney Coal Field, Nova Scotia," by A. O. Hayes and W. A. Bell. This describes an area of 200 square miles immediately to the southeast of Sydney, which has not been examined by a government geologist since Hugh Fletcher mapped the Sydney field in 1895-7. As much information has been gained since that time, principally by drilling, the present survey was commenced by Dr. Hayes in 1917, and finished by Dr. Bell in 1921.

Of the four coal fields of Nova Scotia at Springhill, New Glasgow, Inverness and Sydney, the last is the youngest. The Port Morien part of the Sydney field, with which the present report deals, has been estimated to contain 254,420,000 metric tons of coal in seams one foot or over in thickness.

The survey shows that, among several dozen seams determined in this basin, only four are workable. The lowest, the Tracy seam, underlies an area on land and within workable limits under the sea of 100 square miles. Over only the Eastern half of this, however, is it of workable thickness, from 4 to 6 feet, containing a total amount estimated at 100,000,000 tons. The Spencer seam, next above, is confined to a much smaller area and is quite variable in thickness. It contains from 50,000,000 to 100,000,000 tons of coal in both land and submarine areas. The Gowrie seam, on which the Dominion Coal Company is operating two collieries, Nos. 21 and 22 at Birch Grove, is likewise in the narrow syncline, pitching seaward. It is from five to six feet wide. The Blockhouse seam, above, is nine feet thick. Both these seams are capable of profitable mining in the submarine areas, and the Dominion Coal Company has acquired the mining rights over a large part of both the land and the submarine areas.

Special mention is made of the systematic and well-directed exploration by drilling in this field by Mr. W. N. Macdonald of Sydney. In an appendix is described briefly the Bras d'Or coal district 15 miles northwest of Sydney. Here two workable seams, the Stubbart and the Bonar seams, contained, within the combined land and submarine areas, a total of 35,000,000 tons.

#### POSITIONS OPEN AT OTTAWA

Applications will be accepted up to June 7th by the Civil Service Commission, Ottawa, for two positions on the staff of the Department of Mines.

5367—An Assistant Chemist for the ore dressing and Metallurgical Division, Mines Branch, will be engaged at an initial salary of \$2,100, to be increased at the rate of \$120 annually and supplemented by whatever bonus may be provided by law. University graduation or its equivalent and three years' subsequent practical experience are required of the candidate, who will do analyses and research work in the laboratories of the Branch.

5368—A Junior Engineer, Borings Division, Geological Survey, with an initial salary of \$1,680, will be appointed to make laboratory examinations of deep-well borings. A graduate in geology with some experience in field work is required.

Application forms are available in the post-offices of the larger cities, at any office of the Employment Service of Canada, or direct from the Civil Service Commission in Ottawa.

# NEWS AND COMMENTS

By ALEXANDER GRAY

## Indian Mines, Portland Canal.

The competition for Portland Canal, British Columbia, mining properties is unusually keen. It may be cited, for example, that three international financial firms have asked for terms on Indian Mines and the ground that company controls. It is not the purpose, however, of the Montreal and Toronto owners to part with the property that is undergoing development, where the prospects are reported to be progressively satisfactory. A new compressor plant has just started and a lower tunnel is being driven on ore that is said to average at least \$15 for a distance of about 400 feet. This tunnel will be carried along for a further four or five hundred feet, to points underneath surface outcroppings of excellent grade. Instead of entertaining proposals whereby control would pass out of their hands, Canadian owners have decided upon a policy of development and the provision of a concentrator that can be added to when additions are required. Meanwhile it is likely that the higher grade ore will be shipped to the most convenient smelter, the desire being to make the mine carry some of the cost of development, although arrangements have been made to finance fully the company's requirements. It is pointed out that the lower tunnel is being driven on only one of the known ore-bodies, the values in which are mainly in gold. Not only are Indian Mines putting profitable ore in reserve, but adjoining properties have been acquired by the company and the Premier company. The Northern Lights area is held by the Premier Company, which is driving a tunnel at a depth of several hundred feet below its present workings. With what it has and what it expects—including the possibilities of several properties taken under option—Indian Mines may be reorganized in the near future; but control will rest with Canadians until the milling stage is nearer.

## Mr. Timmins Returns.

When President Noah A. Timmins of Hollinger Consolidated was going aboard a liner at New York, on pleasure bent, an alert reporter rushed to the gangway and informed him the big news was out; Solomon Barnato Joel and associates of London were to purchase control of the premier gold mine of the American Continent for \$30,000,000. It was all fixed, according to Porcupine sources of intelligence. The Barnatos, greatest factors in the diamond world and chiefs of one of the Rand Groups, were ready to close the deal, and it was even asserted that Mr. S. B. Joel had visited Porcupine incognito.

Mr. Timmins did not engage in a lengthy interview with the reporter. He tersely stated: "It might take more than that amount to buy my own interest, were it for sale."

The story was not to be so lightly disproved. It continued to make the rounds, was revamped, embellished, appeared in Wall Street, and London would have it the matter was as good as closed, notwithstanding Hollinger market value at the moment was about \$67,000,000, to say nothing of the treasury surplus.

Mr. Timmins proceeded "en famille" to Rome, thoroughly enjoyed the respite from his responsibilities, saw the Riviera and Paris, and eventually sojourned in London, where he had the pleasure of meeting Mr. Joel, whose

guest he was at one or two events. Here it may be explained that Manager Brigham of the Hollinger is well known to Mr. Joel. At times Mr. Brigham managed individual De Beers diamond mines, and he was manager of Jagersfontein Mine, which De Beers owns. It was perfectly in order, therefore, that Messrs. Joel and Timmins should meet, exchange views, talk mines and mining. Neither discovered that either sought to buy or sell control of Hollinger.

Mr. Joel is a keen sportsman and mining investor. He does not plant millions without due thought—and consultation with principals; and as for Hollinger control, he assumed it was not on the bargain counter at a discount such as the price mentioned represented.

Really and truly, however, he was asked to participate in a recent London flotation. The sponsors for this were satisfactory to Mr. Joel. Upon reflection he decided not to join in that Porcupine undertaking, the shares of which have been soaring to several times their issuing price. No doubt the reports associating Mr. Joel and his colleagues with the entirely mythical Hollinger transaction served its purpose; they helped the London market for the new issue.

\* \* \*

## London Accumulating Canada

Whether or not London sought a majority portion of Hollinger (eleven years after London jettisoned what Hollinger stock Bewick, Morcing took over) there is no denying London's powers of absorption of prospects and properties. Mr. H. G. Latilla is busy with sundry matters. Having eliminated a troublesome element in its Davidson adventure, the Michelson party is less prominent; yet there is satisfaction in self-purification. All the Rochester Veteran proposition is held over there, current market valuation of the shares being a tribute to the manipulative abilities of the principals involved. Part of Monea has gone overseas. John Taylor & Sons and affiliated interests have responded to the "call of the wilds." A market is to be made for Dome shares. The annexes, as it were, are favored, not only in Northern Ontario districts but throughout the Portland Canal. Areas round the Premier Mine of Portland Canal are the vogue. This is attributable in part to the Selukwe holdings of B. C. Silver, concerning which the Selukwe annual report had this:

"An active development campaign is in progress on the B. C. Silver Mines, northern area, comprising exploratory work by diamond drilling, and by driving a tunnel 1,200 ft. in length. On 17th January, 1923, a cable was received stating that an ore formation 43 ft. in width and averaging \$31 per ton over the last 25 ft. had been encountered. Shortly afterwards a pocket of bonanza ore assaying up to \$180 per ton was located. Driving and crosscutting along the formation is proceeding, and the face on 14th March was 205 ft. from Station 312. The recently acquired claim, known as Cascade No. 5, is, report states, apart from any mineral prospects, the natural deep adit level approach to the B. C. Silver Mines claims, and is also of great prospective value as a mill and power site, aerial tramway terminus, and for its water-rights, timber, and other advantages.

# Reported Discovery of Placer Gold in Labrador<sup>(1)</sup>

OFFICIAL STATEMENT FROM THE GEOLOGICAL  
SURVEY, OTTAWA.

As the Geological Survey is receiving from Canadian prospectors and investors many enquiries for information regarding the reported discovery of placer gold near Stag bay, Labrador, it has been decided to make public what information it possesses regarding the reported discoveries and the geological features that have a bearing on the probable existence of placers. The claims that have been staked have been recorded with the Government of Newfoundland; consequently the Geological Survey of Canada has made no field investigations in the area since the discovery was reported, and has no first-hand knowledge of the alleged placers. During the past, however, officers of the Survey and geologists from other institutions have explored the Labrador coast, and a good deal is known about its geological features.

Stag bay lies 30 or 40 miles west of Cape Harrison, north of Hamilton inlet. It is described by A. S. Packard, who entered it, as a wide sound bordered by lofty, terraced hills. Robert Bell<sup>(2)</sup> made observations at points along the Labrador coast. A. P. Low<sup>(3)</sup> along the coast and on lake Melville and more recently (1921) E. M. Kindle on Lake Melville and along the coast south of Hamilton inlet. Our knowledge of the geology of the southern part of the coast is based largely on work done by A. S. Packard<sup>(4)</sup> and by R. A. Daly<sup>(5)</sup>, and of the northern part of the coast by A. P. Coleman<sup>(6)</sup>.

The existence and preservation of placers are affected in large measure by glaciation, for the reason that glaciation, or ice action, tended to carry away and destroy any placers that accumulated before the ice age, and there has not been time enough since then for the new ones to form. Most geologists believe that all except the elevated parts of the very northern stretch of the Labrador coast was intensely glaciated by a continental ice-sheet that moved seaward in a direction at right angles to the general northwest trend of the coast.

Dr. Coleman, who spent parts of two summers in a study of the northern part of Labrador and the adjacent part of Quebec, after briefly describing the plateau of the Canadian shield, says:

"The loftier parts of this tableland rise near the coast from mount Thoresby (2 733 feet) near Nain to Ryan bay near Eoluse harbor (four peaks said to

be from 5,000 to 6,000 feet in height), with a length of about 230 miles from southeast to northwest. It must not be supposed, however, that these higher points form a distinct range of mountains. In most cases they are merely a mountainous fringe on the seaward side of a somewhat narrow tableland, and they are broken up into shorter or longer sections separated by lower areas. From southeast to northwest may be seen the Kiglapaits, north of mount Thoresby; the Kaumajets, near Okak and Mugford, and the highest portion of all, named the Torngats by Daly and others, extending from Saglek bay to Ryan bay, with a length of nearly 100 miles."

Most of Dr. Coleman's work was devoted to the central part of the mountains known as the Torngats. With regard to glaciation of the northern part of the coast he writes:

"The evidence of the glacial action is absent from a considerable area in northeastern Labrador, since the higher tableland and the tops of the mountains which fringe it on the Atlantic side show no marks of having been overridden by an ice-sheet. The area left unglaciated cannot yet be exactly outlined owing to the absence of observations over most of the region; but it is known that along a coastal belt extending from Saglek to Komaktorvik, a distance of 80 miles, there is no appearance of ice action above the valleys. At Nachvak this unglaciated condition is known to reach at least 50 miles inland, giving a driftless area of perhaps 3,000 or 4,000 square miles. The tops of the Kiglapait and Kaumajet mountains to the south and of the Four Peaks to the north, as well as many other isolated peaks, probably rose as nunataks above the surrounding ice.

"The unglaciated character of the higher levels at Nachvak and northward was noted by Leiber and Bell, who remark upon the jagged character of the mountains as incompatible with the passage over them of an ice-sheet. Daly goes more fully into the question and reaches the conclusion that Nachvak glacial ice did not reach higher than 2,100 feet above sea-level. The idea suggested by these writers that the Labrador ice-sheet made its way through depressions in the tableland, such as Nachvak fiord, and reached the Atlantic is not borne out by the writer's observations.

"Though the northeastern peninsula of Labrador was not covered by the great ice-sheet, its depressions were occupied during the Ice age by long and large glaciers which scoured out the valleys and in many places left deposits of boulder clay and moraines. This work seems to have been done, in part at least, toward the end of the Glacial period, as shown by the unweathered character of some of the deposits and of the lower glaciated surfaces; whereas old looking, strongly indurated till in other places was probably laid down earlier.

(5) *Geology of northeast Coast of Labrador: Mus. of Comparative Zoology, Bull. Vol. 38.*

(6) *Geol. Surv., Can., Memoir No. 124.*

"The small existing glaciers may be looked on as remnants of these far greater valley glaciers.

"South of the unglaciated area mentioned above, there can be no doubt that the continental ice-sheet reached the sea, since even hill tops present moutonnée forms and erratic blocks, through striated surfaces are seldom seen except on the lower levels. Distinct moraines and boulder clay are not common, probably because the region was one of erosion rather than deposit but morainic material and till may have been deposited off what is now the coast on the submerged continental shelf."

A. S. Packard says that the "whole Labrador Plateau has been molded by ice to a height at least of 2,500 feet above the level of the sea.... Only at one point near the northern termination of the Peninsula at Cape Chudleigh have the mountains by their altitude escaped the rounding and remodelling action of glaciers." He and others point to the rounded character of the hills, the roches moutonnées, the glacial striae, the lunoid markings and the transported boulders as convincing evidence of glaciation.

R. A. Daly, in describing the coast from Belle Isle to Paul's island which includes Stag bay, says that "from any commanding hill on island or mainland, the eye ranges far and wide over a surface showing everywhere the evidence of universal and profound glaciation. Unobscured by forest, soil, or thick drift, and singularly expanded because of the crystalline clearness of the atmosphere, the view typifies that which may be had in the Laurentian Highlands of Canada or in the Archaean of the Scottish Highlands. It is a great wilderness of innumerable rounded, ice-worn hummocks, generally gneissic in composition. Among the roches moutonnées lie equally countless ponds and bogs connected by the small streams of a most disordered drainage."

Packard, Daly, Coleman, and Kindle call attention to the paucity of glacial deposits other than boulders. The area was evidently, as Coleman states, one of erosion rather than deposition and the great bulk of the loose material resulting from pre-Glacial weathering may have been swept, as suggested, to the sea and deposited on the submerged continental shelf.

It is thus seen that conditions have been produced in that part of Labrador extending from the south end to much farther north than Stag bay similar to those existing in northern Ontario. Both are underlain by pre-Cambrian rocks and both have been subjected to intense glaciation. Geologists and prospectors have learned to look upon northern Ontario as unfavourable ground for prospecting for placers. Placers that may have existed before the Ice age are believed to have been destroyed and scattered by the eroding action of the great mass of moving ice.

A few placers have been formed since the Ice age but they have never paid to work because the gold is scattered through the glacial drift and has been only slightly concentrated in the Recent gravels. It is very unlikely that placers have been formed in Labrador since the Ice age. As has been pointed out, the coast of Labrador, except the very northern part, has been swept clean of nearly all unconsolidated material, pre-Glacial and Glacial, except boulders; there is little likelihood, therefore, of placers having been formed by a resorting of glacial debris, and sufficient time has not elapsed since glaciation for the breaking

down of great thicknesses of rock necessary for the formation of new placers.

Rich placers do occur in some glaciated regions, for example in the Cariboo district of British Columbia, but the Labrador region was more intensely glaciated than the Cariboo. Cariboo is a mountainous region with deep and narrow valleys and the ice-sheet could not move freely because of these deep valleys and because it was hemmed in by mountains. In Labrador the ice could move freely and its scouring action was pronounced. Although it cannot be said that placers will not be found in Labrador, the chances for the occurrence of rich ones seem very remote.

In view of the above some of the statements that have appeared in advertisements of the reported Labrador placers seem improbable. It has been implied, for example, that there may be considerable areas of gravel, 21 feet thick carrying \$100 in gold per cubic yard. Neither does the evidence of the actual discovery of placer gold, as given in advertisements by promoting companies, appear satisfactory. It is apparently based mainly on a statement claimed, in advertisements, to have been made by Ledoux and Company, New York, concerning an assay of a sample of gold-bearing gravel from Labrador. Correspondence, however, with Ledoux and Company has elicited the information that they had been unable to find any record of such a sample having been submitted to them either by H. C. Bellew or Richard W. Edwards.

### A BELLEW CIRCULAR

*The following circular, of recent date, is not likely to hook many "suckers," now that H. C. Bellew has been publicly exposed so thoroughly.*

Montreal, May 15th, 1923.

#### Particulars of Syndicate to Finance Prospecting Expedition

Positive and reliable information has come to me of a very rich deposit of alluvial gold soil in a certain part of the Province of Quebec, which, for the protection of the discoverer, until such time as proper staking can be done, is being kept sacredly secret by the few who know of its existence.

I have been favored with the confidences of the discoverer and know from the geological formation of the district in question that it is entirely likely that the report is authentic.

Therefore, I have consented to organize and equip an expedition that will immediately set out to secure as much of the property as is considered valuable to us.

To do this will require a fund of at least \$5,000.00, and I propose to raise this sum by means of a little private syndicate and, if necessary, to even raise an additional sum of \$5,000.00 as a reserve in case that further capital might be required, but for the present the initial sum will be confined to just \$5,000.00.

There will be one hundred interests in the Syndicate of one hundred dollars each and I am now offering just fifty of these interests to provide this first five thousand dollars. Each member subscribing one hundred dollars will have one claim of at least 200 acres staked and recorded in his or her name and this claim will remain his or her personal property.

There will be at least one hundred claims staked, fifty of these for the individual members of the Syndicate and of the balance at least twenty five claims are to be set aside for the operative members of the expedition as full remuneration for their services, the balance to be held in trust by me as an undivided asset to form the nucleus of a new company in which the Syndicate members will further retain an undivided fifty percent (50%) interest.

A competent Mining Engineer will accompany the expedition and only good ground showing evidences of gold will be staked.

Already several of my friends have subscribed to this fund and it is desirable if favorable consideration is to be given this proposition by you that you will be good enough to let me hear from you by return mail.

Any one may subscribe for one or more interests while they last.

Make all cheques payable to the order of H. C. Bellew, and I will send you a receipt embodying the foregoing and I will personally guarantee the fair carrying out of the undertaking to your entire satisfaction.

H. C. BELLEW.

### PERSONAL AND GENERAL

Col. J. J. Penhale is in Thetford, Que., doing some special work for the Asbestos Corporation of Canada.

Mr. A. G. Langley, resident mining engineer at Revelstoke, B. C., has accepted an invitation to attend and to address the Northwest Mining Convention to be held commencing the 22nd inst. at Spokane. Mr. Langley will discuss the present conditions and the outlook as to mining in the Kootenay section of British Columbia.

Mr. W. A. Carlyle, who was provincial mineralogist for British Columbia during the years 1896-97, and who has since been prominently connected with mining in Spain, England, and Eastern Canada, is in Victoria. He expects to spend the summer in that city.

Dr. Victor Dolmage will take charge of the British Columbia branch of the Canadian Geological Survey, taking the place of the late J. D. MacKenzie. No announcement has yet been made as to the plans of the Survey for field work in British Columbia this summer, but some intimation of what is intended is expected when Dr. Dolmage has had time to settle down to the discharge of his new duties.

Mr. Alexander McEachern, Chief Inspector of Mines, Dominion Coal Company, Nova Scotia, is in Ottawa to give evidence in the inquiry being made by the Senate Committee on Fuel. Mr. McEachern was in charge of No. 2 shaft when it was being sunk and afterwards developed No. 2 Colliery, Sydney, which is the largest colliery in Canada. He should make a very useful witness, as he has had an extended practical experience in coal mining, and has a thorough knowledge of most of the coal fields of Nova Scotia.

Mr. Stewart Troop, who discovered the silver showing on Wigwam Lake in the Gowganda district, Ontario, has severed his connection with the present owners of the property and is now in Moncton, New Brunswick.

Mr. E. G. Riebe, consulting engineer of the Silver Bell Mining Co., has been visiting the Portland Canal Mining Division, B. C.

Mr. J. A. McDonald, a well-known northwestern mine operator, is reported to have bonded the Bayview Group, situated on the west side of the Bear River a short distance from the town of Stewart, B. C. The showings thus far are encouraging, some high-grade silver-gold ore having been uncovered.

Mr. A. W. McDonald, Superintendent of the Department of Industrial Relations, Dominion Coal Company, Sydney, attended the recent quarterly meeting of the Executive Committee of the Nova Scotia Accident Prevention Association at Halifax.

Messrs H. C., W. E., and C. W. Magee, brother mine operators interested in the Patricia and Montana Groups of claims on the south fork of the Marmot River, have returned to Stewart after wintering in Vancouver. Dr. R. E. McKechnie, a well-known resident of Vancouver, is one of the principal owners of these properties, which have been optioned to an English syndicate until July 1st. It is said that, if the terms of the agreement are carried out, \$50,000 will be expended on development this season.

Frank E. Lucas, Economy Engineer of British Empire Steel Corporation is in Halifax in connection with the coal and coke business of the Company.

Mr. A. A. Mackay, of Montreal, has left for northwestern Quebec, where he will commence immediately examination of the property of the Lake Fortune Mining Company in Boischatel township.

Mr. F. W. Guernsey, retiring chairman of the British Columbia division of the Canadian Institute of Mining and Metallurgy, was entertained at a complimentary dinner in Vancouver last week. The newly elected officers are as follows: Mr. Thomas Graham, chairman, Mr. H. G. Nichols, vice-chairman for the Coast district; Mr. M. E. Purcell, of Rossland, vice-chairman for the Interior, and Mr. H. Mortimer Lamb, secretary-treasurer.

M. E. G. Germer, who was formerly the owner of the Colonial Mine at Cobalt, which was subsequently taken over by the Contintenal, has been visiting the property.

### IMPROVED STATISTICAL SERVICE ON COAL

The series of monthly reports on coal statistics for Canada issued by the Dominion Bureau of Statistics is now being prepared in printed form which is much more convenient for reference than the stencil copies formerly distributed. Several new features have also been added. In the text, a review of the coal statistics for the month is presented, and in the tables, the output of coal from Canadian mines is shown by districts, the imports from the United States and Great Britain are given by ports of entry and the exports are shown by ports of exit. Data are given for the month and for the year to date with comparative figures showing the average for the month and the period in the three preceding years. One of the new tables shows the tonnage lost in the coal mines of Canada by Provinces and gives an analysis of the percentage lost by causes including absenteeism, lack of orders, car shortage and mine disability.

It is expected that each issue of the *Monthly Report of Coal Statistics* for Canada will be off the press about six weeks after the close of the month reported. Copies of this report may be obtained, free of charge by those interested, on application to the Dominion Bureau of Statistics at Ottawa.

The movement of iron ore down the Lakes this season promises to be unusually rapid, and it is estimated that the season's output from the Lake Superior field for 1923 will exceed 60,000,000 tons.

## AN ADVANCE IN SUBMARINE COAL MINING IN NOVA SCOTIA

About eighteen months ago, No. 9 colliery, operating on a seam directly overlying that of No. 2, one of the largest collieries in Canada, ceased hoisting coal until the workings of the lower seam were advanced to permit of pillar extraction without undue disturbance of the coal measures above. This work of drawing the pillars in No. 2 has just been begun and from a mining engineer's standpoint it is most interesting. Both collieries are under the sea, the lower seam having a cover of twelve hundred feet. As work on the upper seam will not be resumed for six months yet, or exactly two years from the time mining was stopped, a sufficient number of pillars will be drawn before then to induce a large break. As there are 450 feet of strata between the two seams, the subsidence is expected to be of such a nature that the upper seam will be very little affected. All pillars will be swept out clean and whatever settling of the measures takes place should be uniform, which will prevent the forming of "humps" and strata fracture. When the time comes to draw the pillars of the upper seam, these will be removed by the same method and the eight hundred feet of strata remaining between the coal and sea bottom will, while being allowed gradually to subside, be very little disturbed.

To remove a thickness of thirteen feet of coal with a cover of twelve hundred feet under the sea is a very fine mining problem and one on which many eyes will be focused. It will be years, however, before the pillars of the upper seam, which is six feet thick, will be removed; but once begun they too must be taken out clean to allow uniform subsidence. The first work of this kind was done in Princess colliery, Sydney Mines, where all pillars were successfully extracted under Sydney harbour, the coal there being six feet high. The cover is 1,200 feet. This experience has given great confidence to mining in other parts of this under-sea coal bed. There is very little doubt in the minds of mining men that successful drawing of all the pillars will take place. But on the other hand there is always the uncertainty of the unknown and unknowable quantity in mining an under-sea area that haunts the mind long after all coal of pillar sections has been won. What may take place before the whole seam is exhausted, is an ever-present question which no mine manager or mining engineer can afford to ignore. It is not enough to follow methods of mining that will allow the sea bed to settle so that no break will take place through which water might filter and fill the mine. The barrier pillars between collieries must be sufficiently thick to withstand enormous pressure, should such a thing occur as the sea breaking in. Experience in Cape Breton mining has taught that barrier pillars have been left sufficiently strong to resist pressure when large collieries have had to be flooded, but the working of the mine had so affected the overhead strata as to weaken and open them, which allowed large quantities of water to pour through into adjacent collieries. This is a real source of danger, which can only be guarded against by leaving boundary pillars undersea so thick that the overlying measures will not be affected.

If a straight line were drawn between the two points on the shore-line where the two outside shafts are sunk it would measure about twenty miles. In this distance there are now less than fourteen collieries, and five others projected. The coast on this shore-line is deeply indented with bays and harbors, but the collieries are situated as close to the shore, on points jutting out into the sea, as is consistent with safety. From these points of vantage the coal-field is attacked, and as the three subordinate basins formerly known as the Lingan-Victoria, the Sydney Mines and Bras D'Or, and the Glace Bay basins are now known to

unite and form one great undersea basin, it can be readily understood that mining science has here a great problem for experiment. To remove the coal seams lying nearer the sea bottom without endangering the collieries in operation or the coal seams underlying, is a big task; but the mining engineers of Cape Breton are equal to it.

In this they are ably supported by the British Empire Steel Corporation, which when advised of the proper mining policy, stopped one of their largest collieries for a period of two years that this policy might be put into full operation at once. The company that will do this can be trusted to use the methods of mining that will tend to maximum production and minimum loss of coal in the mine, with due regard to the success of the mining industry in the days to come.—J. M.

## DISCOVERY OF \$26,000,000 WORTH OF PLATINUM DREDGING GROUND IN THE URAL MOUNTAINS\*

Before it was impossible to operate in Russia, when it was vitally necessary to obtain adequate quantities of this precious metal for sulphuric acid manufacture, electric contact points and other purposes, every effort was put forth to increase production. Great advance in price was a stimulus to studying peculiarities of occurrence with the object of enlarging reserves and cheapening and hastening production.

Platinum occurs in the Ural Mountains in those small localities where the ultra-basic rocks are exposed. It has not been successfully worked *in situ*, nor are there veins capable of economic exploitation. It is sparsely distributed in the olivine rock associated with chromite. Disintegration of the olivine liberates the fine round grains of platinum through erosion and it finds its way into the beds of the streams which flow off these olivine bosses. A stream flowing over such rock might also contain platinum down stream. Irregularities may be discovered, for in certain instances reconcentration has occurred. Further, since the deposition of platinum, the stream may have changed its course, and it is a problem to determine where the platinum is at this time.

Besides fifteen dredges of construction too light for the purpose most of the work was done by hand. A group of seven or eight men would be allocated a plot of ground 70 x 70 feet. Then they would sink a shaft through the gravel and clay to bedrock, pumping out the water and wherever possible joining their workings with others, should there be a bedrock drainage tunnel. The sandy clay paystreak six inches to one foot above bedrock in favorable localities, contained the platinum richly concentrated, sometimes so that it could be picked up with a spoon. Kytlim river on the Nicolo Pavda estate was such a locality, within a few miles of the divide between Europe and Asia, with 5,000 men so employed, each group washing out its own platinum and turning it over to the company office, at a reduced price, to compensate for facilities furnished, and in some parts for a central washing plant operated by hand. The ground remaining was fast becoming unprofitable. Steep creek grade, old timbers, abundance of clay of the worst kind, and many big boulders seemed to make dredging hazardous.

\*By R. S. Rostford, Member American Institute of Mining and Metallurgical Engineers, Engineer in Charge, "Research" Narrative 57, Engineering Foundation, New York.

The two miles of Kythin river flowed into the Lobva. Many shafts had been sunk in the latter, across the stream bed, with negative results by local operators and by exploring parties from other countries. Apparently not realizing the source of the platinum, previously described, the upper extension had been missed. A series of shafts at sufficiently close equal intervals, at right angles to the probable direction of bedrock flow of the platinum pay streak, disclosed that there had been three streams which had united to produce the deposit. This fact discovered, lines of shafts determined the limits, average value, depth and conditions to be encountered, in exploitation.

The assumption before this discovery was that the much larger Lobva river had brought in so much gravel and had been so swift that much of the platinum had flowed away and had been so diluted as to yield only the traces hitherto found. It was further assumed that the platinum, being heavy, round and easily concentrated when freed from the clay, had not been carried in large quantities far beyond the junction, which their prospecting seemed to confirm.

Lines of shafts extending across the valley, sunk to investigate previous results, only confirmed those results. However, continuing to extend a line of shafts to the bedrock rim, which seemed to be close, at a point beyond other prospecting shafts and below what appeared and is now known to be a bench, the bedrock receded,—and then we came into the platinum a few shafts farther on. It was a glorious feeling, especially as there is fully five miles of it over 750 feet wide tucked in under the bench, averaging from top to bottom over 80 cents per cubic yard at present prices. The upper end was much richer.

We were not quite out of the woods yet, but the stuff was there. Other problems were solved. Four dredges have been operating and two others under construction, three of them modern American dredges, electrically driven from a wood-fired power plant in the forest. The product was about a quarter of a ton of platinum annually, and when all the dredges are in operation, will be about two-thirds of a ton, at a trivial working cost. Shares went from 67 to 450 during this period, and dividends increased continuously.

## PRODUCTION OF LIGNITE IN GERMANY

It is of interest to note that the 1922 production of lignite registers an increase of 57 per cent over that of 1913. This development is due to the necessity of replacing fuel for the lost bituminous coal areas and for the coal applying to the reparation deliveries. Lignite is far from being a satisfactory replace fuel because its heating qualities are only about one-third as great as bituminous coal, and it requires, when briquetted, about 50 per cent more shipping space.

However, it is used with good results for household heating purposes, and also by electrical plants; the glass, porcelain, and textile industries; chemical works, etc. Its greatest economic value lies in its consumption in the vicinity of place of production.—U. S. Commerce Reports.

## LIQUID OXYGEN EXPLOSIVE

Results of an investigation at the Bureau of Mines experiment station, Pittsburgh, Pa., indicate that liquid oxygen explosives may be used to advantage, especially in the lessening of blasting costs, in iron, salt and other mineral mines and quarries. Preliminary tests seem to indicate that liquid oxygen explosives are not suitable for use in gaseous and dusty coal mines, although the experiments offer some hope of so modifying these explosives as to make them suitable for certain uses in such mines.

There are a number of advantages gained by the use of liquid oxygen. One great advantage in using liquid oxygen as compared with dynamite and black blasting powder is the low cost per unit of material blasted. As liquid oxygen explosives are made at the place of consumption, the danger common in the transportation of other explosives is eliminated. In the use of liquid oxygen explosives there is practically no danger of premature ignition. The danger of mis-fires is eliminated by a wait of 30 or 40 minutes after the fuse is lighted, when practically all the oxygen will have evaporated. Another advantage in the use of this novel type of explosive in mining operations is the elimination of the danger of unexploded sticks in shoveling and subsequent handling of ore or coal going out of the mine. Other sources of danger eliminated are handling and thawing processes such as are necessary with frozen dynamite and the hazard from lightning or fire when stored in magazines.

### Disadvantages

The use of liquid oxygen explosives in mining and blasting operation has, however, certain disadvantages. Because of the rapid evaporation, liquid oxygen must be used quickly and within a definite time after the hole is charged, thus limiting the number of shots that can be fired in any one place and making the firing of a group of shots, although possible, more difficult. In this regard, however, it may be said that in one mine using liquid oxygen explosive a round of 28 holes was blasted at one time. The use of liquid oxygen explosives virtually requires the installation of a local liquid oxygen plant involving a considerable first cost. This liquefying plant must be kept running regularly, if liquid oxygen is to be obtained at low cost, as the main cost of making liquid oxygen is in the power used. The arranging of practical methods of use of liquid oxygen explosives in an ordinary mine or quarry is difficult because the miners or quarrymen have been accustomed to using dynamite or black powder.

The chief item in the cost of liquid oxygen explosives being the cost of the oxygen, the Bureau of Mines considers that there is hope of a decided reduction in cost through improvement in liquefying machines.

### Rising Cost of Nitrate Explosives

The gradual increase in the cost of producing standard explosives and the resultant increase in the saving possible through the use of liquid oxygen explosives, the Bureau of Mines considers will tend to overcome the natural opposition of miners and quarrymen who have always used other explosives.

Under the stress of necessity of providing nitrates for military explosives, the development in Germany, after the beginning of the war, was rapid. Liquid oxygen explosive was used in large quantities in the Upper Silesian coal mines, which were non-gaseous, in tunnel work, in subway and excavation work in cities, in iron mining — not only in Germany, but also the French iron mines of Lorraine which had been seized by Germany — and also for destroying French steel plants.

French officials in the Briey iron district believed that the explosive introduced by the Germans had come to stay.

An investigation in September, 1920, by George S. Rice, chief mining engineer of the Bureau of Mines, disclosed that there were in operation 136 liquid oxygen plants at coal, iron potash, and salt mines throughout Germany, having a total capacity of 3,797 liters of liquid oxygen per hour. Allowing for losses, and calculating the time operated; a net total of 2,430,000 liters or 5,346,000 pounds, of oxygen was used, equal to 8,000,000 pounds of dynamite.

#### Portable Plants

One of the most interesting features of the development had been the design and construction of small portable liquid oxygen making plants of a capacity of only 3 to 5 liters of liquid oxygen per hour. Such plants have been constructed for moving about on trucks, thus making liquid oxygen much more available for small operators.

A further important development in the use of liquid oxygen explosives in Germany has been made through the pre-arrangement of a shot-firing circuit, by means of which, it is claimed, as many as 28 shots have been fired in a round.

Under present conditions in the United States introduction of the explosive will have to depend on demonstrated merits and advantages in comparison with explosives already in use.

Experiments on liquid oxygen as an explosive began at the Bureau of Mines testing station at Pittsburgh, Pa., in April, 1917. An appropriation of \$15,000 for investigations of this nature during the coming fiscal year has been made by Congress. The results of experiments so far made are summarized in Technical Paper 294, which may be obtained from the Department

#### LARGE GOLD NUGGETS FROM SMALL VEINS

In a rugged out-of-the-way region on the ocean side of the Coast Ranges, in Monterey County, California, gold nuggets have been found of such size as to suggest that this was once a favorite retreat of the proverbial goose that laid the golden eggs. Matter-of-fact prospectors, however, have sought to find the veins from which such masses of gold, loosened by the weather, were washed into the stream beds. Their search has not been successful, and J. M. Hill, a United States geologist of the Department of the Interior, in a report just published suggests that the nuggets came from rich superficial pockets in very small veins, and that no large and rich deposits are likely to be found by deep mining. The Coast Ranges of California, unlike the Sierra Nevada, are not rich in gold, and the occurrence of these large nuggets is exceptional and illustrates the fact, known to many prospectors, that the discovery of a few large nuggets does not necessarily indicate the existence of a rich deposit of gold ore in place.

The Jardine Mining Company in Montana, has commenced to treat low-grade gold ore containing arsenic, consequent upon the present high price of arsenic. This event directs attention to the gold-arsenic ore of Hastings county, Ontario, which have remained unworked for many years, though formerly profitable. There is no intimation as yet that the owners of these deposits consider them workable at present.

#### BOOK REVIEW

MERCURY ORES, by Edward Halse. Monograph of the Imperial Institute, published by John Murray, 50-A Albermarle Street; London; W. I.—100 pages—price 5 s. net.

This volume is one of the Imperial Institute's series on mineral resources, and deals particularly with occurrences within the British Empire, while mentioning more briefly deposits in foreign countries. The geological association of mercury ores with igneous intrusion and hot springs is noted as universal, the ore being found mainly in sedimentary rocks near an intrusion.

Canada's only mercury deposits so far discovered are near Kamloops Lake, B. C., in a zone 30 miles long and 2 miles wide. Some ore carrying 0.75% mercury has been mined, but it is of too low a grade to be worked at present.

New Zealand is the only part of the Empire in which there is at present active mining of mercury ore. At Puhupuhi in the North Island there has been determined 60,000 tons of ore averaging over 1% mercury, and there is some expectation that a million tons of ore can be won by open-cut mining. An experimental reduction plant is being erected.

The principal mercury mines of the world are in the Idria and Monte Amiata districts of Italy (formerly in Austria), at Almaden in Spain, and in California. The Italian mines are operated by the government. The Idria deposits were discovered in 1470 and have been worked ever since. The ore occurs in fissures in a bed of Triassic shale, up to 66 feet in thickness, with 0.75 to 1% mercury. The ore producing zone of Monte Amiata covers 150 square miles, within which are numerous small mines with ore carrying up to 1% mercury.

The Almaden mine in Spain has been worked for centuries, and supplies nearly one-third the world's annual need. It is now worked to a depth of 1300 feet, in ore of increasing richness, impregnating bands of slate and quartzite of Silurian and Devonian ages. The ore is of high grade, said to average 8%, and the present annual production is estimated at 1000 tons of mercury.

There are numerous small known deposits of mercury ore in Mexico, which are worked periodically. The same can be said of the United States, where the low tenor of the ore in most of the mines (averaging about 0.5% mercury) allows of activity mainly during periods of high prices.

This volume almost duplicates that recently issued by the Imperial Mineral Resources Bureau. Might it not be better, in future, to concentrate effort on a single volume.

Production of by-product coke in the United States in March reached the unprecedented total of 3,256,000 net tons, which was 16 per cent greater than the February output, and 5 per cent more than production in January. The estimated present capacity of by-product ovens is 3,725,000 tons per month of 31 days. Thus the output indicates production at the rate of 87.4 per cent of total capacity and an average of 105,042 tons per day, which is an increase of 4,692 tons or 4.7 per cent over the daily rate of production in February. Of the 71 plants in existence 64 were active and 7 idle.

## PETROLEUM AND GAS IN ONTARIO

"Natural Gas in 1921" and "Petroleum in 1921," by R. B. Harkness, Commissioner of Natural Gas, are contained in the 80 page report comprising Vol. 31, Part 5 (1922) of the Ontario Department of Mines report. The 71 pages devoted to natural gas demonstrate the wisdom and utility of creating the office of Commissioner, which was, to a large extent, forced upon an unwilling public by the alarming diminution of natural gas supply in the gas fields of Southwestern Ontario. The production during 1921 was 8,532 million cubic feet.

The Commissioner of Natural Gas is a true conservationist. By means of legal regulations, as well as by educative propaganda and research, he is gradually putting to the most effective use the remaining supply of natural gas. This is illustrated in his report by certain practical instructions in the effective use of gas; by the prohibition of free gas supply, which inevitably entails waste; and by the compulsory adoption of proper metering devices. A systematic record of results from wells drilled in Ontario is a useful feature of the report.

In order to obtain an impartial judgment on the various conflicting claims that arose after the appointment of the Commissioner, a consulting engineer of note, Mr. Samuel S. Wyer, of Columbus, Ohio, was engaged to examine the gas field in Kent County, the principal one in Ontario. His report, quoted in full by the Commissioner, commends the practical measures for conservation already adopted and suggests further measures.

The brief report on the oil fields shows a production for 1921 of 172,858 barrels, thus marking the gradual decline. A map marking the oil pools, past and present, of Southwestern Ontario is included.

## DIAMONDS FROM ARKANSAS

Nearly 6,000 diamonds have been found in diamond mines in Arkansas, and some stones have been picked up in other States. The diamond fields of Arkansas are in Scott County, where a valuable diamond was first found in 1906 by John Huddleston, a farmer. The mule he was riding happened to kick up a stone of unusual brilliance, which caught his eye. He dismounted, picked up the stone and put it in his pocket, and a few days later the performance was repeated. The stones were sent to Tiffany of New York, whose expert said "diamonds," and soon afterward Mr. Huddleston is said to have sold his 40-acre farm for \$36,000.

Though the diamond field of Arkansas has never achieved greatness, it has yielded a considerable number of fine stones, the largest weighing  $21\frac{1}{4}$  carats and another stone weighing 17.86 carats. Many of the Arkansas stones are as fine as any found elsewhere and, according to George F. Kunz of Tiffany's, they include a large proportion of white stones, most of them of high grade in color and brilliancy and freedom from flaws. Doctor Kunz further states, in describing several of the yellow, brown, and white stones from Arkansas, that "these are absolutely perfect and are equal to the finest stones found at the Jagersfontein mine or that were ever found in India."

A few of the Arkansas diamonds, it is said, have sold for as high as \$600 a carat. Most of them, however, are small and have been placed in private and museum collections. Diamonds do not occur in clusters, nor

are they gathered together in the volcanic "pipes" or mother lodes in which they are found. The average recovery in the African diamond mines is about one carat to two tons of ore, and the average recovery in the Arkansas mines has been about one carat to eight tons of ore.

## COKING OF OIL SHALES.

Results of all past assay retort studies in the oil shale laboratory of the Department of the Interior at Boulder, Colorado, have been tabulated and will serve as the basis for a report to be prepared by engineers of the Bureau of Mines. In connection with this work, some very interesting information regarding the coking of different shales has been accumulated. The sample of Australian shale which yields over 120 gallons of oil to the ton has only a slight tendency to coke in the retort. The 60-gallon Elko, Nevada, shale has no tendency to coke. The 65-gallon massive shale from DeBeque, Colorado, shrinks to half its size and apparently melts down in the retorting process, and the resultant coke adheres most tenaciously to the retort walls, being difficult to remove. Another massive shale from the same locality, but 600 to 700 feet higher in the series, yielding about 60 gallons of oil to the ton, shows only a slight tendency to coke. The 50-gallon Soldier Summit shale has no tendency to coke, and the 34-gallon standard DeBeque shale shows only a slight tendency to coke. It is thus apparent that the richness of the shale is no indicator of its coking tendency. An interesting problem opened up here is to determine if possible what characteristics of the shale indicate tendency to coke and measures may be taken to prevent coking. The particular DeBeque shale that cokes so badly seemingly represents the richest workable deposit in that district, so the solution of this problem is likely to have results of great importance.

Analytical distillations were made on the shale oil produced by the assay retorts from the Australian shale and on the oil produced by running to coke Australian shale produced by a commercial plant. The results are exactly parallel to results of similar studies on American and Scotch oils.

## INDUSTRIAL ITEMS

"Jackhammer" drills are described comprehensively in the 32-page bulletin, No. 4046C, just issued by the Canadian Ingersoll-Rand Company. This bulletin is a second edition, revised. It describes both dry and wet patterns, hand and mounted types, and is fully illustrated. It can be had on request by those interested.

"I See a Coal Mine," is the title of a little story of coal, from pit to boiler, told briefly by Walker Enright in a tiny volume issued by the Taylor Stoker Co., Ltd., Toronto and Montreal. The moral of the story is, of course, that Taylor Stokers, with their continuous, automatic feeding of fuel to the boilers, make better use of the coal than other means of firing.

Jos. W. Hays, consulting engineer of Michigan City, Indiana, who has up to the present conducted his practice with the aid of a corps of assistants, has now organized Jos. W. Hays and Associates, who will carry on the work under the firm name. The firm's speciality will continue to be steam plants.

# THE MINING DISTRICTS

BY THE JOURNAL'S CORRESPONDENTS.

## NORTHERN ONTARIO

**Quinze Power.** — The firm of Beatty & Morrow Limited, have secured the contract for the construction of the 20,000 h.p. hydro-electric installation on the Quinze. Power from this installation, which is expected to be available before the end of 1924, will be used very largely for the Porcupine mines. Contractors have already started work, and the surveys of the transmission line are under way.

**Strike Vote.** — It came as rather a surprise to learn that the Porcupine Miners' Union had decided to take a strike vote. Voting started on May 17th and will be continued until the 20th. It is understood that so far the response of the miners has been very small and that comparatively few votes have been cast.

**Cobalt.** — The report of the Nipissing for April shows that the company mined ore of an estimated value of \$192,987, and shipped bullion of an estimated value of \$204,485. The low-grade mill treated 6,858 tons and the high-grade plant 202 tons. The refinery shipped 304,178 ounces of bullion, which is estimated at 67-3/8c. per ounce. The most important development during the month was the extension of veins No. 251 and No. 304, which showed substantial improvement as stoping progressed.

La Rose has completed its crosscut into the old Violet workings at a depth of 630 feet in the new shaft. Where the vein was encountered it showed from 4 to 8 inches of high-grade ore, with good values in the mill rock. The company has made arrangements to have its ore milled by the Mining Corporation, and shipments will be commenced in a few days.

**South Lorrain.** — A good deal of disappointment is felt over the condition of the South Lorrain road, which is in an almost hopeless state. The Government has spent a lot of money on this road and no doubt feels that it has met the desires of the operators; but unfortunately for the latter, while a good deal of money has been spent most of it has been spent where it would do the least good. Last year work was confined very largely to the part of the road that needed it least so that this spring teams were unable to get through with loads.

**Kirkland.** — The Tonopah Mining Company has started work on the King-Kirkland, Wood-Kirkland and Moffat-Hall. On the King-Kirkland development work is being undertaken on the 400-foot level, and it is understood that the shaft will be continued to 1,000 feet. On the other two properties the work for some time will be confined to the surface.

Teck-Hughes expects to start crosscutting on the 1,100-foot level within a few days, and will open up the 9th and 10th levels. Development in all parts of the mine has been very satisfactory and the grade is the highest of any gold mine in Northern Ontario. Production in April was approximately \$88,000.

Machinery for the new mill of the Lake Shore is beginning to arrive on the ground, and practically

the entire plant is on order. Construction work is already started, and it is expected to have the new mill in operation before the end of the year.

Kirkland Lake Proprietary, which has undertaken a big development campaign in Kirkland, has also taken an interest in the Moneta property in Porcupine. A recent report of Mr. H. S. Denny speaks very encouragingly of the possibilities in Kirkland. The shaft is being sunk to 800 feet, and the company is now amply financed to carry it to the point where production can again be started.

Preparations are being made to sink on the Town site property, which has been taken over by Mr. A. D. Miles, representing John Taylor & Sons of London, England. The same company has taken an option on the Queen-Lebel property and will continue the shaft from 60 to 300 feet, where lateral work will be undertaken.

The Continental will instal an electrically driven plant on its Kirkland properties. The shaft has been sunk to a depth of 150 feet by hand, and some encouraging values have been encountered.

**Porcupine.** — Work has been resumed on the Clifton property in Porcupine, sufficient funds having been raised by the underwriting of 250,000 shares of treasury stock at 30 cents a share. The company proposes to continue its development programme.

The Goldale has started work on the sinking of its shaft from 650 to 1,000 feet. During the sinking no work will be done on the 500-foot level. The Company found two good shoots of ore on the 500-foot level and it is hoped that there will be an improvement at 1,000 feet.

The Coniagas is also preparing to sink a new shaft on the Newray and it is stated that this may go to 1,000 feet.

The power shortage of this spring is reflected in the April output of the Dome, which amounted to \$160,111 as compared with \$260,000 in March and \$366,000 in February.

The Dome Lake is now receiving electric power and has commenced the unwatering of the mine. The shaft is to be continued from 600 to 1,000 feet, and four new levels will be opened up.

It is learned that the McIntyre is considering the sinking of a new shaft which will reach an ultimate depth of 5,000 feet, and that the company is also considering the building of a new mill on the north side of Pearl Lake. With depth the company is getting the downward extension of an increasing number of Hollinger veins, and on the McIntyre they appear to be of higher grade than on the Hollinger. An official of the company has stated that within a few years the McIntyre should be able to equal the Hollinger output. The present mill is now treating 1,000 tons a day, and the grade of ore is higher than when a smaller tonnage was being treated.

**Ontario Companies in Quebec.** — Several of the Northern Ontario mining companies are arranging to start work in Ronny township in Northwestern Quebec. The Dome has a large acreage under option, which will be investigated this summer. La Rose has recently taken options on approximately 500 acres of ground a short distance south of the Noranda properties, while still further South the Coniagas has several claims. The Lyman-Quebec syndicate has sent in a gang to carry on prospecting work, while a number of other syndicates and companies are preparing to operate. The extension of the Powell vein is reported to have been found half a mile further south, and several new discoveries in other parts of the camp are reported. The district appears to be important and this summer's work should go a long way toward proving it.

### BRITISH COLUMBIA

**Stewart.** — Work on the upper levels of the Fish Creek Mine, American Mining & Milling Co., has ceased and the compressor and other plant is being moved to facilitate the driving of a long crosscut tunnel with a view to locating the veins at depth. This, it is reported, is in line with the recommendation of G. T. Jackson, mining engineer, who examined the property, in company with W. R. Tonkin, last year.

**The Copper Bounty.** — News of the Dominion Government's bounty of 1½ cents per pound on bars and rods manufactured from Canadian copper for use in Canada is enthusiastically received in British Columbia. S. G. Blaylock, general manager of the Consolidated Mining & Smelting Co., is quoted as stating that it is a step in the right direction, as has been proven by the inactivity of the \$200,000 copper plant of the Trail smelter. The placing of oxide of antimony, one of the newest products of Trail, on the same basis as zinc, may lead, it is said, to its production as white antimony instead of in metallic form as at present.

Noble Binns, president of the Associated Boards of Trade of Eastern British Columbia, and F. A. Starkey, Commissioner for the same Association, are extremely pleased and are quoted as stating that, if the tariff changes work out as would appear likely from first indications, the copper mining industry of the province will be greatly stimulated.

**Trail Ore Receipts.** — Ore receipts at the Trail smelter, Consolidated Mining & Smelting Co., for the last week of April, totalled 11,290 tons made up as follows:

| Company                                | Tonnage. |
|----------------------------------------|----------|
| Black Rock, Northport . . . . .        | 152      |
| Bosun, Silverton . . . . .             | 34       |
| Company Mines . . . . .                | 10,235   |
| Lone Pine, Republic, Wn. . . . .       | 223      |
| Quilp, Republic, Wn. . . . .           | 162      |
| Rosebery Surprise, New Denver. . . . . | 52       |
| Silversmith, Sandon . . . . .          | 328      |
| Surprise, Republic, Wn. . . . .        | 104      |

11,290

During the first week in May there were received at Trail 11,519 tons, the details of which follow:

| Company                                              | Tonnage. |
|------------------------------------------------------|----------|
| Black Rock, Northport, Wn. . . . .                   | 40       |
| Bell, Beaverdell . . . . .                           | 47       |
| Howitt, Silverton . . . . .                          | 41       |
| Knob Hill, Republic, Wn. . . . .                     | 211      |
| Lone Pine-Surprise-Last Chance, Republic Wn. . . . . | 441      |
| Quilp, Republic, Wn. . . . .                         | 213      |
| Surprise, Republic, Wn. . . . .                      | 51       |
| Silversmith, Sandon . . . . .                        | 221      |
| Standard, Silverton . . . . .                        | 172      |
| Company Mines . . . . .                              | 10,082   |
|                                                      | 11,519   |

**Canada Copper.** — T. H. Marshall, of New York, was the purchaser of the entire assets of the Canada Copper Corporation which are centred chiefly in the Province of British Columbia and the State of Washington. They were put up at auction in the Court House of Vancouver City on May 7th and Mr. Marshall's bid of \$2,000,000, the only one received, was accepted. A cash payment of \$10,000 was made and part of the \$2,500,000 bonds, the default of interest on which led to foreclosure proceedings, will be used for the purpose of the purchase. The amount due on the bonds inclusive of interest was given as totalling \$2,926,780. Mr. Marshall is understood to represent Messrs Hayden Stone & Co. of New York, and it is understood that these formalities are preliminary to the assumption of control of the mine and plant at Copper Mountain and Allenby, B. C. by the Granby Consolidated Mining & Smelting Co.

**Slocan Relics.** — A rifle and old-time prospector's pick, used by Eli Carpenter, the discoverer of the Slocan, have been presented to the Associated Boards of Trade of Eastern B. C. for display at the City of Nelson with other souvenirs of historic interest.

**Ainsworth.** — The Cork-Province mine and mill have resumed operation. Work on the 400-foot level is proceeding in both directions on the hanging wall side of the vein. General underground conditions are reported as excellent and it is expected that production will be under way in the course of a few weeks.

**Lardeau.** — W. B. Smith, of Spokane, and I. N. Eirnhart, of the Federal Silver Mining Co., Troy, Montana, are reported to have taken a bond and lease on four crown-granted mineral claims twelve miles from the head of Kootenay Lake in the Lardeau District. The agreement calls for the payment of \$45,000 within five years. Development is to start immediately. Mr. Smith says that a very wide vein is in sight within which on the footwall there is an 18-inch stringer of high-grade grey copper ore in white quartz.

**Slocan.** — Judgment for \$10,000 in favor of the Canadian Bank of Commerce against the Lucky Jim Zinc Mine has been granted by the Supreme Court of Canada. For the Company it was stated that the debt probably would be paid and the defendants were allowed six weeks to do so.

**Cariboo.** — Further rich placer ground is reported to have been found near Quesnel Lake, and about three miles from Cedar Creek, Cariboo District.

**Taxation Ruling.**—Two important rulings have been made by the Taxation Department of the Minister of Finance of British Columbia with reference to the assessment of the mining industry. It is declared that a mill treating customs ore only is exempt from taxation on the land; and that a mill treating ore from its own mine, even if it is treating customs ore in addition, is exempt.

## NOVA SCOTIA

**Troubles of the "Reds".**—The "Reds" are on the run and revolution no longer hangs threatening over the heads of the mining villages of Cape Breton. The foot race began with Malcolm Bruce, who for seditious utterances had to leave Glace Bay rather hurriedly. A wise man once said that "the wicked fleeth when no man pursueth," and Sam Jones said, "Yes, but he runs faster when chased."

The chasing and running business was not, however, confined to Bruce of Toronto. Bell, another Toronto importation who replaced Editor Cotton on the *Labor Herald*, to please his small coterie of friends made a strong personal attack on Silby Barrett, International Board Member of the U. M. W. of A. Barrett resented it and appeared in the office of the *Labor Herald*. Bell at first grabbed a part of the office stove, but thought better of it and "beat it." Now Barrett says men who talk revolution should not be afraid of a black eye.

A night or two later the mounted constables of Nova Scotia entered the headquarters of the U. M. W. at Glace Bay and searched it for seditious literature, and carried away the Red flag of the May Day demonstration. The home of J. B. McLachlan was also searched for seditious literature. Some Sydney houses were entered where it was known that Soviet literature was kept and bundles of it were seized and sent to the Attorney General's office in Halifax. These bundles contained printed propaganda and pamphlets in the Russian and other foreign languages. A general clean-up is to be made and from this on no privileges will be granted workmen who are out to violate the laws of the country that protect and shelter them.

This action has had a decided effect on the residents of the Sydney and Glace Bay districts, and sober thought is returning to men who without reflection permitted themselves to be carried away by the wild words of worthless men. The "Bulls of Bashan" no longer bellow, and the sublime secretary, J. B. McLachlan, of District 26, U. M. W. of A., whose word yesterday "stood against the world," today finds "none so poor as do him reverence." The mining villages laugh and wonder "how the mighty have fallen;" but mourners do not go about the streets.

Nova Scotia has had great patience with the "Red" agitators, but when the religious and national feelings of its citizens were outraged by real Russian Reds and others of the same type and the "Key Industries" of the Province were threatened with disaster the Government rose to the occasion and is now in action. "Run them out of the Province," is the common cry, and there is much meaning behind it. It was fast reaching the point where the moderate, tolerant citizen was beginning to realize that for him there was just

one of two things to do, either to quietly leave his native Province or gird himself and assert his right to enjoy the liberty and peace the British flag offers. The first was beneath the thought of a red blooded Nova Scotian, so the issue was joined and consternation suddenly smote the Red camp. It is hard to say which was the more surprised at the sudden change in affairs, the peace loving citizen or the boasting blackguard paid to spread discord and create unrest.

**Steel Plant Busy.**—The Sydney Steel Plant is running full blast, with all departments in operation. The blast furnaces made new records last month, and are in a fair way to beat these this month. The bulk of the steel output, is going into rails, wire products, and material for the order for one thousand cars on which the Eastern Car Works at New Glasgow is now working. The billets for this work are reduced in size so that the machinery of the New Glasgow plant can easily handle them.

Newfoundland labor is finding the Sydney Steel Plant a very favorable source of employment, as upwards of one hundred men from the Colony were placed in one day recently.

**Housing Scheme.**—The British Empire Property Company has been formed for the purpose of selling the houses owned by the British Empire Steel Corporation to their employees. The business agent is Thomas Cooke, Sydney Mines. The aim of the Company is to help the workmen of the coal and steel industries of Sydney and the colliery districts to secure their own homes. This will lead to a settled and contented class of workmen with an interest in the villages in which they live, and a feeling of responsibility that rests upon all good citizens with high ideals. It will, so far as the companies are concerned, reduce the labor turnover, develop a professional class of workmen who will find their trade profitable, tend to lessen labor agitation, and generally bring about desirable social and industrial conditions at the collieries and the steel plants.

The houses are to be sold on easy payments, and workmen will be encouraged and helped to purchase and possess their own homes. On all houses costing \$1,000 or under a 10 per cent deposit will be made, and the rentals rated to have the building paid off at the end of ten years. Where it is found that workmen desire to pay larger monthly rentals they will be permitted to do so, and in this case the first deposit may be less than 10 per cent. An elastic system may be developed with experience, and it is thought that this will tend to show workingmen that there is a strong desire on the part of the steel and coal companies to aid them to be home builders, enjoying all the benefits to be derived from owning a home. Later on the system may be extended and workingmen may find, after all, that there is a common interest that unites the employer and employee of any industry.

Some years ago the Dominion Coal Company decided to sell its houses and made a fair beginning. A few miners bought, but the business was not placed in the hands of a competent business man who would push it and the scheme fell through. The success of the present policy is already almost assured, for houses have passed over to workingmen in every mining village and applications are being sent in daily. Mr. Cooke is an enthusiast, with wide powers and a large knowledge of working men. There is little doubt that he will succeed and that eventually a great change will be brought about in the status of the working men and their attitude to their employers.

**Co-operative Store.**—About the same time that the Dominion Coal Company commenced to sell their houses, the Nova Scotia Steel Company at Sydney Mines adopted the same policy, but with better success. They succeeded in interesting their workmen, with the result that a large number of them now own their own homes. The company benefited by a fairly well contented class of workmen, who set about trying further to improve their conditions. They established or rather built up, a co-operative store business, which is one of the great successes of the Province in that line. Last year's turnover amounted to \$756,000, the dividends on purchases averaging 12 per cent. The building and stock are free of debt. After many fruitless attempts to operate co-operative stores in the Glace Bay district, Sydney Mines Co-operative Society took over the Glace Bay store and in a few years has more than trebled the business. No greater asset can be added to an industrial village than a class of workmen who are trained to understand business, and this training is most thorough in a well organized and well conducted co-operative store business. The Nova Scotia Steel Company have profited greatly by their venture in helping their workmen to their own houses, and there is no doubt that the Dominion Coal and Steel Companies will now have the same reward.

**Mr. Marsh Resigns.**—Karl H. Marsh, Chief Engineer of the Dominion Iron, Steel & Coal Co., and the Nova Scotia Steel & Coal Co., will sever his connection with these Companies on the last of May to take up work in his home land, the United States. Mr. Marsh has made a host of friends since coming to Cape Breton and it is with deep regret that these bid him good-bye.

Although only 38 years of age, he has had a wide and varied experience since leaving college. Since coming to Cape Breton, he has had to do with nearly all classes of construction at the Sydney steel plant, the Wabana iron mines, Newfoundland, at the collieries, the shipping piers and the Sydney & Louisburg Railway. After graduating from the State College of Pennsylvania in 1909, Mr. Marsh went immediately into active engineering with A. G. McKee, Consulting Engineers, Cleveland, Ohio. The following year he went with the Republic Iron & Steel Co., Youngstown, Ohio. For a year he was engaged with the Dominion Iron & Steel Co., Sydney, and then returned to Cleveland, and spent a year with the Cromwell Engineering Co., consulting engineers. The next five years were spent as Superintendent of Construction with the A. G. McKee Co., and then he spent one year as Chief Engineer of the Hamilton Furnace Co., Hamilton, Ohio.

For the past three years, Mr. Marsh has been Chief Engineer in Sydney.

### PLATING WITH CHROMIUM

At the recent meeting of the American Electrochemical Society in New York, Mr. F. C. Kelley of the General Electric Co. described a method of applying a protective coating of chromium to iron and steel. The object to be plated is packed in a powdered mixture of alumina and chromium the latter being at least 95 per cent pure. This mixture contains 55 per cent of chromium, the 45 per cent of alumina acting merely as a diluent, to prevent an excess of chromium adhering to the iron at the high temperature (1300 to 1400 degrees, C.) to which it is heated. The chromium is plated on the iron only in an atmosphere of hydrogen.

### SASKATCHEWAN MINERALS

The province of Saskatchewan is not yet of great importance as a producer of mineral wealth, apart from its lignite mines; but it has distinct possibilities, and one of these, a ceramic industry, has already been inaugurated successfully. The Province has no mines department as yet, so that Bureau of Labour and Industries records, in its annual publication, the chief facts about mineral production. The second Annual Report, covering the period ending April 30th, 1922, was published recently, and from it the following information is extracted.

#### High-Grade Clay Deposits

Saskatchewan is well provided with an abundance of clays for the production of a wide variety of clay wares. The more general types that have been investigated or are in use at the present time are pottery clays, (several grades), stoneware clays, fire clays, shales, ordinary clays. The adaptability of these clays for the manufacture of stoneware, earthen cooking ware and sewer pipe is beyond question, as proven by its prolonged use in the manufacture of these lines at Medicine Hat during the past eight years.

The Ceramic Department of the University of Saskatchewan has conducted tests on clay from two promising localities. A stoneware clay from Knollys, of a grey-white colour, has qualities in working and burning that compare with the best. Ball clay from a deposit near Willows station on the C. P. R. gave similarly good tests, after washing to remove concretionary iron.

#### Sodium Sulphate

The pulp and paper industry of Canada require some 40,000 tons annually of sodium sulphate. This chemical is contained in abundance in numerous deposits in Saskatchewan, and several companies are now producing it commercially. Only those deposits that contain the mineral almost pure, say 96 to 98 percent, and are close to existing railways can hope to produce in competition with the artificially made chemical. Drying of the mineral before shipment is a pre-requisite to success.

#### The pre-Cambrian Area

The northern third of Saskatchewan lies within the pre-Cambrian "shield," notable for its production of metallic mineral wealth. No railway touches this area, and it is in the main unexplored. During the seasons of 1920 and 1921 a provincial party explored the region around Lac La Ronge, on the southern border of the pre-Cambrian area. Few, if any, prospectors have worked in this region, apart from those in the Amisk Lake area near the Manitoba boundary, where the discovery of the Flin-Flon and Mandy deposits in Manitoba stimulated some activity. The canoe routes are good, and large areas of unprospected ground are thus made accessible for exploration.

### FERRO-SILICON IN BLASTING EXPLOSIVES

Occasional use has been made of ferro-silicon in the manufacture of blasting explosives during the past few years, states the United States Bureau of Mines in Bulletin 219. It is added as a sensitizer and also serves to increase the specific gravity of the powder.

Ferro-silicon is an alloy of silicon and iron of indefinite composition and properties, the proportion of the two components varying widely. It is invariably crystalline in structure, though distinct crystallization is absent in alloys containing 50 percent or over of silicon. The exact number of distinct silicon-iron compounds is in

dispute, the number mentioned ranging from two to five.

Impurities in ferro-silicon are largely a function of impurities present in the raw materials from which it is manufactured. It is made commercially either in the blast furnace or the higher-temperature electric furnace. That prepared by the first method contains 20 percent or less of silicon, the richer alloys being made by the second method. In the blast-furnace method the charge consists of iron oxide, siliceous iron ore, and coke, the reduction being effected by the carbon. In the electric-furnace method two kinds of charges may be used. These may be either wrought iron, steel, or cast-iron turnings, quartz, or sand, and charcoal: coke, or coal; or a charge of siliceous iron ore, quartz, or sand, and charcoal. Iron turnings are generally preferable to iron ores.

### SALES OF CRUDE FELDSPAR IN THE UNITED STATES

Reports made by producers of crude feldspar in the United States in 1922 to the Department of the Interior, through the Geological Survey, show sales amounting to 114,200 long tons, valued at \$812,400, an increase of 24 per cent in quantity over the sales in 1921.

The average price was \$7.11 a long ton. In Maine feldspar averaged 10.06 a long ton, in New Hampshire \$8.33, and in North Carolina \$5.77.

"CANADIAN MINING ENGINEER, holding responsible position in United States, desires opening in Canada. Thoroughly familiar with all details of mine development and successful record in mine operation. Must give present employers reasonable notice. Reply; Box 583, Canadian Mining Journal, Gardenvale, Que."

### PURCHASE OF GOLD ORES

The attention of prospectors and others is drawn to the provision in the Mining Act of Ontario authorizing the Department of Mines to purchase parcels of gold ore taken out by prospectors and others in developing or working mining claims. Arrangements have been made by which such parcels of gold ore, whether large or small, will be accepted by the Temiskaming Testing Laboratories at Cobalt, and paid for according to the schedule provided for the purpose. The Laboratories are operated under the auspices of the Department of Mines.

This offers a first class opportunity for testing the value of ores on a large scale, and also of turning ore of good quality into money for carrying on further development work. By special arrangements, on less than carload lots, freight rates on the T. & N. O. Railway are reduced 50 per cent.

The Laboratories are also equipped for working out the best methods of treatment for gold or silver ores of a refractory or unusual character.

Full information as to treatment charges, schedule of payments, etc., can be obtained from the undersigned, or from A. A. Cole, Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

THOS. W. GIBSON,  
Deputy Minister of Mines.

Toronto, 12th March, 1923

"Assay supplies of all kinds for field and mine use. Send us an estimate of your requirements and we will attach prices. Special "sheet iron gold washing pans, postpaid to any address, \$1.00."

## LYMANS, LIMITED

Chemical and Assay Apparatus

MONTREAL

## The SYLVESTER Hand Car Motor

will save  
time and  
money for  
you

Can be attached to any standard hand car.

If you are already using pump or push cars on your surface tracks it will pay you to install this efficient outfit on them.

The extra work your men can accomplish and the time saved will soon pay for them.

We manufacture a complete line of hand cars — motor, pump and push types. Our equipment is in use on every railroad in Canada and giving excellent service.

Let us send a copy of our catalogue illustrating and describing our entire line.

- Summary Report of the Mines Branch, 1920.  
The Mines Branch maintains the following laboratories in which investigations are made with a view to assisting in the development of the general mining industry of Canada.
- Fuel Testing Laboratory.**—Testing value of Canadian fuels for steam raising and production of power gas; analyses, and other chemical and physical examinations of solid, liquid and gaseous fuels are also made.
- Ore-Dressing Laboratory.**—Testing of Canadian ores and minerals, to ascertain most economical methods of treatment.
- Chemical Laboratory.**—Analysing and assaying of all mineral substances and their manufactured products. Copies of schedules of fees, which are slightly in excess of those charged by private practitioners, may be had on application.
- Ceramic Laboratory.**—Equipment is such that complete physical tests on clays and shales of the Dominion can be made, to determine their value from an economic standpoint.
- Structural Materials Laboratory.**—Experimental work on sands, cements and limes is also undertaken.
- Applications for reports and particulars** relative to having investigations made in the several laboratories should be addressed to **The Director, Mines Branch, Department of Mines, Ottawa.**
- Summary Report.** The annual Summary Report of the Geological Survey is now printed in parts. Applicants should, therefore, state what particular geologist report is required, or what subject they are interested in.
- Memoir 108.** The Mackenzie River Basin, by Charles Camsell and Wyatt Malcolm.

- Applicants for publications not listed above should mention the precise area concerning which information desired.
- The Geological Survey will, under certain limitations, give information and advice upon subjects relating to general and economic geology. Mineral and rock specimens, when accompanied by definite statements of localities, will be examined and their nature reported upon.
- Communications should be addressed to **The Director, Geological Survey, Ottawa.**

## Select Your Ventilating Equipment on the Basis of Measured Efficiency

Would you buy power plant equipment that is only half as efficient as it should be? No? Then why use ventilating fans of unproven efficiency when a large percentage of your power goes for their operation.

The efficiency of Canadian Sirocco Mine Fans is as definitely known as that of your engines. Every unit of energy delivers a definite quantity of air at any required pressure. Our guarantee of this is found in hundreds of satisfactory installations over a period of forty years.

Canadian Sirocco Engineers have collected data that will enable them to give valuable cooperation regardless of what your ventilating problem is. They are at your service. Write for information and descriptive bulletins.

Offices  
Newark, N. J.  
280 Broadway, N. Y.

**Balbach Metals Corporation**

ESTABLISHED 1922

280 Broadway

New York

Buyers of Gold, Silver, Lead and Copper Ores;  
Lead Residues, and Copper Residues.

Sellers of Casting Copper Ingots; Desilverized  
Lead; Antimonial Lead; Copper Sulphate;  
Gold; Silver; Platinum, and Palladium.

**PLATINUM**

BOUGHT AND SOLD

**GOLDSMITH BROS.**

**SMELTING & REFINING CO., LTD.**

TORONTO

NEW YORK

CHICAGO

SEATTLE

**Deloro Smelting & Refining Co.  
LIMITED**

*SMELTERS AND REFINERS PRODUCING*

Silver Bullion

Cobalt Oxide and Metal

Nickel Oxide and Metal

Refined White Arsenic

"STELLITE" High Speed Tool Metal

Head Office and Works:

DELORO, ONT.

Branch Offices: 26 Albermarle St., London W., Eng.

**What Are Your  
Flotation Troubles?**

Have you difficulty in obtaining flotation oil which exactly meets your requirements? Do you have trouble in obtaining uniformity among different lots?

Our technical staff, always at your service, will gladly co-operate with you in determining the grade of flotation oil best suited to your needs. This done, we can supply it.

Hercules Pine Oils, manufactured under strict chemical control, can be furnished you in lots which never vary from the original specifications.

Write for quotations and an interesting booklet on flotation.

**HERCULES POWDER CO.**

Wilmington, Delaware

SALES OFFICES:

New York, N. Y. Duluth, Minn.  
Chicago, Ill. Joplin, Mo.  
San Francisco, Calif. St. Louis, Mo.  
Salt Lake City, Utah Chattanooga, Tenn.  
Birmingham, Ala.

Distributors for Canada  
Canadian Engineering Ltd., Montreal

**HERCULES  
Flotation Oils**

*Produced Under Chemical Control*

**PERFORATED METALS**

FOR EVERY AND ALL  
PURPOSES IN ALL METALS

Elevator Buckets (plain and perforated)

Conveyor Flights and Trough, also

General Sheet Iron Work

"Light and Heavy Steel Plate Construction."

**HENDRICK MANUFACTURING CO., CARBONDALE PENN. U.S.A.**

And in All Other Canadian Cities

## INDEX TO MINE AND MILL SUPPLIES

Addresses of advertisers whose names appear in the following classified index, may be found upon reference to their advertisements. An alphabetical index to advertisers will be found on the page facing the inside back cover. The following regulations apply to all advertisers:—One-eighth page, every issue, three headings; one-quarter page, every issue, six headings; one half page, every issue, six headings; one half page, every issue, twelve headings; full page every issue, twenty-four headings. Buyers who are unable to find in the in the classification here given such machinery supplies as they desire are invited to write Service Dept., Canadian Mining Journal, Gardenvale, Que., who can in all probability, refer them to proper sources.

# THE CAMERON VERTICAL CENTRIFUGAL PUMP

## *For Mine Service*

The Cameron Vertical Centrifugal Pump is another development for the mining industry carrying all the distinctive features of Cameron design.

The unit consists of a Cameron double suction volute Centrifugal Pump direct-connected to a vertical motor. The pump and motor are both fixed rigidly to steel frame work so constructed that the complete outfit can be lowered down the mine shaft guides.

Vertically split casings and bearings give easy access to the few parts subject to wear or requiring adjustment.

An amply proportioned Kingsbury Thrust Bearing equipped with centrifugal oiling device prevents all possible chance of bearing trouble.

This type of pump is designed in capacities from 2,000-10,000 G.P.M. With a pump of this large capacity at your service there is little chance of serious flooding that might result in temporary abandonment of your mine.

# MORSE CHAINS

*A few of the Morse chains in use at the Raymond Lead plant*

Using chain drives speeds up production,  
 cuts belt expense and overtime wages and  
 operates with practically no repairs.

*Write for Booklet*

CANADIAN AGENTS

**Jones & Glassco, Regd.**

MONTREAL, TORONTO.

O. W. Ludwig, Plant Superintendent of the  
 Raymond Lead Co., Chicago, says:

"Thirteen years of service without a repair is our experience with two 100 H.P. and ten 20 H.P. Morse Silent Chain Drives.

"When we moved into our present plant thirteen years ago, we installed the present Morse equipment of silent chains for our two lead mills and ten hydraulic pumps. We had always previously used leather belts, but not without considerable trouble. For instance, if the operator was not careful—and gave the motors too great a load, the leather belt would slip and in some cases burn out. While with the Morse Chain Drive we overload them at times up to 15 H.P. without the slightest trouble.

"When we used leather belts on the hydraulic pumps, if a pump packing suddenly gave way, the water would squirt all over the pump as well as adjoining pumps, causing the leather belts to get wet. This often necessitated a shut-down on 3 to 4 pumps to dry out each belt, thus causing a loss of time by the men, which resulted many times in paying overtime to catch up on the work. Of course, with our Morse Chain Drive we have no such trouble—this positive drive prevents slippage and is not affected by water.

"Leather belts lasted us 2 to 3 years at the most, while our Morse Chain Drives have already lasted 3 to 4 times that long and seem good for many more years. So Morse Drives have cut our expense materially, speeded up production, cut out overtime wages and saved floor space, for they operate on shorter centers."

## ENDURANCE Forged Steel Balls

Backed By a  
Record of Performance

If efficient and economical grinding service is essential you should order ENDURANCE GRINDING BALLS.

ENDURANCE will materially reduce your grinding costs and save you unnecessary annoyance and cost.

Prompt shipment on receipt of your order.

**Canada Foundries & Forgings, Limited**  
Welland, Ontario

## For Tunneling— Sullivan Water Drifters

**T**HE Imperial Government Railways of Japan are using many **Sullivan Water Drifters** in their heavy tunnel construction work. The selection of Sullivan drills was made after long and thorough tests with several competing types, on the basis of Cutting Speed, Air consumption and repair economy.

Discriminating rock drill users everywhere know the consistent, dependable character of **Sullivan Water Drifter** performance. **Sullivan Drill** engineers are pioneers in the design and construction of modern rock-drilling machines.

# Ontario's

# Minerals

PROVINCE OF ONTARIO

DEPARTMENT OF MINES

HON H. MILLS, Minister of Mines

## Mineral Areas.

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favorable for the occurrence of minerals, 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver mines of Cobalt occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

## Economic Minerals.

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario:—actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluor-spar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, Portland cement, brick and tile, meet every demand.

## Mineral Production.

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1921 to be worth \$48,128,387, of which the metallic production was \$27,574,202.

The following figures show the rapid growth of Ontario's mineral industry by five-year periods since 1891:

| Year.          | Value.      | Year.          | Value.       |
|----------------|-------------|----------------|--------------|
| 1891 . . . . . | \$4,705,672 | 1906 . . . . . | \$22,388,383 |
| 1896 . . . . . | 5,235,003   | 1911 . . . . . | 41,976,797   |
| 1901 . . . . . | 11,831,086  | 1916 . . . . . | 65,308,822   |

## Dividends.

Dividends and bonuses paid to the end of 1921 amounted to \$23,140,734 for gold mining companies, and \$84,388,185 for silver mining companies or a total of \$107,528,919.

## Mining Regulations.

A miner's license costs \$5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of \$2.50 or \$3.00 per acre, depending on location in unsurveyed or surveyed territory.

## Assay Office.

The Provincial Assay Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

## Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

# Adding Impetus To The Development Of Mining

The development of Canada's enormous natural resources will affect her whole future. Her vast mineral wealth, as yet practically untouched, is to day attracting world-wide interest from far-seeing investors.

It is appropriate that the Imperial Bank, whose policy has ever been to concentrate exclusively on Canadian affairs, should be powerfully furthering that interest. This Bank, by placing branches at strategic points throughout the mining districts, has materially aided the whole industry.

Those who contemplate becoming connected in any capacity with mining would be well advised to take advantage of this Bank's facilities.

## IMPERIAL BANK OF CANADA

Peleg Howland, President.

A. E. Phipps, General Manager.

### HOLMAN

## Stretcher Bar Hoists

This well known minor speciality of Messrs. Holman Bros., Camborne, England, is an exceptional labor saving device for underground haulage and winding. Its extreme flexibility, as regards position in which it can be worked, whether from a horizontal, vertical or angle position bar, make it a wonderful time and cost saver in any mine.

## A BILL TO IMPEDE MINING

The Senate of Canada has before it a Bill whose passage would interfere very seriously with the mineral industry. Senator Boyer, of Rigaud, Que., has introduced Bill D., *An Act to amend the Explosives Act*, as follows:

"Section seven of *The Explosives Act*, chapter thirty-one of the statutes of 1914, is hereby amended by adding thereto the following as subsection (3) thereof:—

"(3) Notwithstanding any other provision contained in this Act, no regulation made by the Governor in Council under this Act shall authorize the issue of, and the Minister shall not issue, any license for the establishment location or maintenance of a factory or magazine within two miles of any other building, structure, or premises, except licenses for continuing the maintenance of such factories or magazines as have been established, located and maintained under licenses issued before the date of the coming into force of this subsection."

The meaning of this Bill is plain. It would place every powder magazine in the centre of an isolated area of approximately sixteen square miles. Every mine would have to build its powder house at least two miles away, and probably much further, and to maintain a road for that distance. A hardware merchant selling explosives would find it almost impossible to comply with the regulations, as it would be very difficult for him to find within reach the requisite area of sixteen square miles in the centre of which to set his magazine. The proposed Act is ridiculous, and should be promptly rejected by the Senate at the next reading.

The present *Explosives Act* has been carefully formulated by men with wide and thorough knowledge of the requirements. Under its provisions the manufacture and use of explosives has been made as safe as is humanly possible. There will be found, no doubt, good reason to modify some of the regulations and to add new ones as time goes by; but these changes and additions can safely be left in the hands of the federal and provincial technical officers whose duty it is to supervise and regulate the use of explosives. These technical staffs are of adequate size, they comprise men with unquestioned qualifications for their work, and their record in performance of their duties shows that the public has been adequately protected from the undoubted dangers inherent in the manufacture and use of explosives.

Senator Boyer's Bill is a mischievous and meddling piece of proposed legislation. The Senator lives at Rigaud, Que., not far from the factories of Northern Explosives, Limited. This may account for the mental bias that has promoted the formulation and presentation to the Senate of Bill D. It is incumbent upon the mining men of Canada, as those that would be most seriously affected by the passage into law of such a measure, to see that it is either withdrawn or defeated.

## EAST AND WEST

The Canadian Institute of Mining and Metallurgy has a very important asset in the energy and good will of the members of its British Columbia Division. We print on another page the annual report of the Secretary, Mr. H. Mortimer-Lamb, which appears this week also in the Institute's *Bulletin*. Its careful perusal will repay the attention of those interested in the Institute's welfare, as well as of those who wish to do their part in directing the growth of Canada's mineral industry along rational and sound lines and in preventing undue sectionalism.

As the report points out plainly, apathy is one of the best marked characteristics of Institute membership at present. A considerable number of Western members have banded themselves together to combat this evil, and the past year's record gives a decided promise of final success. These members have faced their problem squarely and find that, as with the Institute at large, long distances and the proportional expense of travelling and a wide diversity of occupation tend to prevent the united and continuous personal effort without which no Institute activities can be fully successful. They have proposed means to overcome these difficulties and have put some of them into effect. The fact that the registered attendance both at the Annual General Meeting of the Division and at the General Western Meeting of the Institute in Vancouver was approximately the same as that of the Annual Meeting of the Institute in Montreal is sufficient to indicate that the British Columbia Division is one of the most active parts of the Institute. The genuine interest of Western members is attested by the fact that the expenses of the General Western Meeting were met by the Division, without recourse to the Institute's coffers. This is an evidence of good faith that should be noted by members in the East.

The British Columbia Division has come into being by a process of devolution. The fact of the geograph-

real separation of the mining districts, east and west, cannot be ignored with impunity. There are local interests and local conditions that can be dealt with only by a local organization. Nevertheless there is a community of interest from Atlantic to Pacific quite sufficient to bind the local units into a strong and powerful Institute. It is these common interests that are the especial concern of the Institute Headquarters. The British Columbia members have announced by word and deed, their interest in the affairs of the Institute at large, and on every possible occasion they make it plain that they are determined to preserve and to develop further the present means of coöperation with Headquarters.

Judging by the proceedings of the Annual Meeting in Montreal last March, where the British Columbia members were without direct representation, the members of Council and the private members of the East have failed to grasp the full significance of the Western members' activities, which are not only held somewhat in suspicion but are not rated at their true worth. The *Canadian Mining Journal* is involved in this judgment, and we freely confess it. Three thousand miles constitutes a distance it is difficult to bridge merely by means of the mails. For ourselves, we hope to find a means whereby the Western point of view and Western activities will be more accurately and more adequately represented in our pages. For the Institute, we trust that the energies and good will of the British Columbia Division will be used as a means to forwarding the general interests of the Dominion's mineral industry.

### KEELEY

In the first of a series of "Letters from South Lorrain" that we print today, Mr. Murray gives briefly the history of that silver camp of rising fame. This is virtually the story of the determined efforts, now well known to the mining public, of one man, Major J. Mackintosh Bell. In commenting on "The New Keeley Stock" in these pages two months ago, we failed to do justice to the proved resources of this mine, and made a prognostication that has, fortunately, failed so far to materialize.

On the result of Major Bell's good judgment and tenacious purpose, we do not need to dwell; the Keeley mine of today tells the story. Our conclusion made in March, and not yet established in fact, was that Major Bell's financial associates had decided to put the new Keeley stock "on the market" in Canada, with all that such a move involves. Both financial sponsors of the Keeley are well-known "market" men, and the signs pointed marketward. Fortunately, we say, our conclusion has proved so far to be wrong, and we hope our prediction will never be fulfilled.

It is incumbent upon the mining engineers of Can-

ada to prevent by every means in their power the financial manipulations conducted in the names of the mines they manage.

### EFFECTIVE REGULATIONS IN BRITISH COLUMBIA

In his address at the international mining convention at Spokane, which appears on another page, Hon. Wm. Sloan, Minister of Mines for British Columbia makes some interesting observations on the measures adopted by his government to prevent the public issue of fraudulent or doubtful mining stocks. He points to the well-known fact that during former mining booms in British Columbia (particularly, we take it, that at Rossland) the public were "gouged" to such an extent by dishonest promoters that genuine mining development suffered for years afterward, and indeed only now, a quarter of a century later, has fully recovered.

Though there is no "Blue Sky" law, Mr. Sloan testifies that regulations now in force are adequate to the need. All promoters are required to submit to the scrutiny of the resident government mining engineer of the district in which their property is situated, prospectuses and other such statements designed for publication. If these statements are inaccurate or misleading, the Minister of Mines has authority to publish the facts. This threat of publicity in a case of attempted fraud is, Mr. Sloan says, sufficient to deter fraudulent mining schemes.

This statement by British Columbia's Minister of Mines has decided significance for those interested in the mineral industry of Ontario and Quebec, whose citizens are at present without adequate protection from dishonest mining stock promoters. The "Blue Sky" law in Ontario is not to be applied to mining promotions until next September, and only then by special proclamation. Meantime the hucksters of worthless mining script are to be allowed free rein.

The preventive measures in the Ontario act are, in their essence, the same as those that are said to be effective, and yet not burdensome, in British Columbia. It is not a perfect law; few laws are perfect; but it might have a very salutary effect during the coming season, which threatens to produce a crop of dishonest and senseless promotions that will choke the growth of the honest ventures in the same fields.

Judging by the public utterances of the premier of Quebec and some of his colleagues, the provincial Government wishes to throw its weight on the side of honest mining development. This might well be accomplished by a simple regulation modelled on that of British Columbia, which avoids the opposition stirred up by the term "Blue Sky" while effecting the desired result.

Whatever the means adopted, the men of the mining industry should unite in self-defence against those

who are at present preying upon the public in the name of the industry and making the name of mining to stink in the nostrils of thousands of Canadian citizens whose money would otherwise be available for finding and developing Canadian mines.

### AN UNDISCHARGED RESPONSIBILITY

The damage done to legitimate issues of stock of industrial undertakings as well as of sound mine promotions is indicated clearly in the pages of our daily newspapers. Last week a prominent paper, known better for its large circulation than for any evidence of sound judgment in its financial pages, carried a display advertisement of mining stock of very doubtful character, and at the same time warned the public, by means of a cartoon on another page, against the angling tactics of dishonest mine promoters. Which bit of evidence are we to believe? Again, the newspaper that has, probably, the best financial pages of any daily in Canada has carried, successively and in the same position as well as in the same typographical style, the advertisements of this same doubtful mine flotation and then of a well-established hydro-electric power company. What sort of service is it that this highly respectable daily is giving its readers? Our financial papers are guilty of exactly the same lack of discrimination. The moral is obvious; publishers with any intention of honest service to their readers must consult men conversant with the truth about mining finance if they are to avoid these pitfalls.

### FIRES AND AEROPLANES

The forest fires are running in the North. Press despatches and private information show that, already this season, someone has been careless in each of several localities. There is evidence to show that this year, as never before, there is to be made a determined and concerted effort to keep the fires at a minimum, so we can hope that these first fires will but add energy to the application of preventive measures.

Last year the Ontario Forestry Branch surveyed, by means of sketching from aeroplanes and by occasional landings, an area of 16,000 square miles, of which little was known previously, between James Bay and the Canadian National Railways on the north and south, and the interprovincial boundary and the Mattagami River on the east and west. The "Aerial Forest Type Map" on a scale of four miles to the inch that has resulted is a revelation in two ways; it shows how good a map can be made, cheaply and quickly, by this means and it discloses the fact that, south of the swampy land surrounding James Bay, about one-third of the area has been swept by forest fires. Neither the prospector nor the lumberman have travelled much within this little known area, and yet fire has wrought wide spread destruction.

The services of the airman are to be used extensively in preventing, detecting and fighting forest fires during the coming months, both in Ontario and in Quebec. His services as a surveyor are not so well known to the public, and the new map of the Ontario Forestry Branch referred to may mark the inauguration of a definite determination of our resources in timber and pulpwood that will stimulate their preservation from fire and their proper use.

There is much that the aerial surveyor might do for the progress of the mineral industry. The geological surveyor and the prospector in Ontario and Quebec now travel "blind" through the woods, seldom knowing what is in store for them a hundred yards ahead through the trees. A topographic map such as this "Aerial Forest Type Map" would be an inestimable advantage to these adventurers on foot, and would certainly save many times its cost. The use of the aeroplane as an aid to the geologist and the prospector remains still, however, a matter to be determined by mutual consultation and concerted experiment. It has great possibilities.

### VERS LIBRE

(Inspired by the advertisements of F. C. Sutherland & Co.)

This is free verse—

*Vers libre*—

Emancipated from rhyme,

But yet not

Totally

Devoid of meaning.

Not at all.

Into the rotunda of the King Edward

Casually dropping,

There met I a very

Receptive person.

Said: "If

" You had now an income of 50,000

" Iron men

" Annually accruing to you

" From the Hollinger Mine,

" You would not feel

" Too darned badly, now would you?"

Said he: — "Not to any

" Very large or varied extent."

These were his words.

" Go to," said I "and

" Come upstairs with me,

" And

" I'll show you maps, plans,

" Etcetera, of a mine that has Hollinger

" Skun a mile."

He came.

Although this is very

Free verse,

I shall go no further.

J. C. M.

## Developments in Gold Mining in Manitoba

by R. C. WALLACE.\*

At the beginning of summer operations a short statement of the prospects in gold mining in this province may be in order. Following the field operations of last season, some of which were disappointing, there has been a dull period in mining affairs. It must now be noted, however, that work is progressing quietly but very satisfactorily in the two main areas where gold is being sought, and that very considerable interest is being taken by outside capital in properties already partially prospected, as well as in prospecting for new finds.

### Herb Lake

In the Herb Lake field, in the east end of the mineral belt north of The Pas, the main operations are on the Bingo property, which lies northeast of, and practically adjacent to, the Rex mine. Development work on the Bingo is being financed by London capital, under the direction of Mr. Joseph Myers. There has been in-

ment has yet been made. The Rex has suffered from financial vicissitudes, and everyone interested in the district would like to see it in strong hands. The property itself is attractive from many points of view.

### Elbow Lake

In the same field there is an occurrence of silver in galena which is now being investigated by American interests. Diamond-drilling will be necessary in order to explore this property. In the Elbow Lake field, in which there was a considerable amount of exploration work done last summer, work is still in progress on the Murray property, on which the Hollinger interests held an option last summer. The work is financed in eastern Canada, and the intention is to continue the shaft, and to drift underneath the lake westwards from the line of last summer's operations. A diamond-drilling programme has also been discussed, the extent of which

Bingo Mine, Herb Lake, The Pas District, showing New Power House, Headframe, and 1200 cords of wood for use this summer.

stalled by the Engineering Equipment Company of Montreal during the latter part of the winter months a complete equipment for developing the property, and work is now practically under way underground. The equipment includes a 100 H. P. Inglis boiler, a 60 H. P. Inglis boiler, a Sullivan air compressor with 709 cub. ft. capacity, a Waugh drill sharpener 3 Waugh hammer drills, and complete general equipment. Mine buildings have also been erected, and development work will proceed from the 200-foot level by drifting 200 feet and then crosscutting to the parallel veins closely adjacent to the main vein. The shaft will then be sunk to the 500-foot level, and the main and other veins will be explored at that level. The company is conducting operations in an efficient manner, and if their development work proves successful they will strengthen considerably the district as a whole.

It is generally believed that the Rex has recently been taken over by a company whose name would guarantee real development of this mine, but no announce-

ment will doubtless depend on the success of the present operations.

The other main area in which work is proceeding is the Rice Lake field, east of Lake Winnipeg and approximately 100 miles northeast of Winnipeg. Here the important work is being done on the Luleo property, north of the Hole river, where operations have been carried on during the past two years by a group of New York business men, under the name of the Selkirk Gold Mining Company. They are operating on the largest width of quartz, in a shear zone, on which underground operations are being carried on in the province. It is not expected that ore will be found over the whole 30 feet of quartz, and surface sampling indicated that special attention might be paid to that part of the shear zone near the walls. Approximately 1,000 feet of underground work has now been done, at the 125-foot, 210-foot and 310-foot levels, and the 20-stamp mill on the property will be used this summer for test purposes. This mill will be scrapped later and a suitable mill of larger capacity installed, if the operations give results to justify large

\*University of Manitoba, Winnipeg.

scale mining. The company is well equipped financially and a successful outcome of their operations would mean much to the Rice Lake district.

Work is also going on at the Gold Pan, well known in the past for its spectacular ore. Pittsburg interests have the property on lease, and are engaged in exploring it. A 5-stamp mill is being erected to handle the output for the immediate future.

nipeg river, and railway and power facilities to this field would the more readily be extended to the Rice Lake district later, if the demand became insistent. 2,000 feet of diamond-drilling has now been done, in shallow holes, and the management is satisfied with the results to date.

In Northern Manitoba no further work on the Flin Flon property has yet been announced. There is a

Luleo Mine, Rice Lake District, showing Mine and Mill Buildings.

### Copper Properties

This article deals specifically with gold mining development. A word about copper prospects may assist in giving a clearer picture of metal mining development as a whole. The much welcomed rise in the price of copper has placed the development of the copper bearing areas of Manitoba within the realm of practical possibility. Work has been going on since the beginning of this year in diamond drilling the Devlin-Martin copper nickel group north of Lac du Bonnet. This is to some degree a key district to the Rice Lake field as well, lying as it does between the Rice Lake area and the new Manitoba Power development on the Win-

very tangible interest in other copper properties in the surrounding district. The Baker-Patton group has been optioned within the last month, and other prospects are now being investigated. During the winter parties were in the Kississing (Cold) lake area on a silver hunt, and they report a large outcrop of copper sulphide, which will be looked into this summer. Developments in copper would immediately stimulate gold mining as well in all the districts.

The present season opens with some very substantial work being done in the two main districts, with mining capital definitely interested, and with some organised plans to prospect for new properties.

### PRE-GLACIAL WEATHERING IN NORTHERN ONTARIO

In the current issue of *Economic Geology*, J. B. Tyrrell draws attention once more to examples of pre-glacial weathering in Northern Ontario, on account of a statement by A. R. Whitman that "residual soil of pre-glacial age is thus far unreported from the surface overridden by the Pleistocene glaciers of Ontario". Mr. Tyrrell says:

"In a letter published in the number of *Economic Geology* for July-August, 1920, pp. 453-454, I drew attention to the existence in Northern Ontario of pre-glacial oxidation and decomposition of the rocks, and gave instances of such decomposition from the Porcupine District and from the Matachewan District fifty miles to the southeast of it. Other instances might have been cited, such as a residual deposit near Sturgeon lake which was worked for a short time as a placer mine, and the glaciated surface of gossan near the Creighton mine, but the two instances mentioned in my former letter seemed quite sufficient to exemplify my point.

In *Economic Geology* for June-July, 1922, Dr. A. P. Coleman, late professor of geology in the University of Toronto, and one of the ablest students of glacial geology, gives a number of instances of the occurrence of residual soil of pre-glacial age in different parts of the Province of Ontario, extending from Michipicoten, north of Lake Superior, southward to Toronto and Niagara.

"But perhaps the most interesting record of the occurrence of pre-glacial oxidation in northern Ontario

was given by Dr. J. Mackintosh Bell in a paper which he read before the Institution of Mining and Metallurgy of London, on the 16th of February last, describing a silver vein in the Keeley Mine in the South Lorrain District, 20 miles southeast of Cobalt, in northern Ontario. This vein, and others in the immediate vicinity, are in pre-Cambrian greenstone and diabase, and consist for the most part of calcite, smaltite and native silver. The vein itself and the adjoining country rock is shown to have been oxidized and decomposed to a depth of 420 feet at least, which was the greatest depth then reached in mining, and that this oxidation was undoubtedly pre-glacial in age.

"In *Economic Geology* for June-July, 1922, Dr. A. P. W. Knight, Assistant Provincial Geologist of the Province of Ontario.

"In view of the above records of facts, it will be necessary for those dealing in any way with ore bodies in northern Ontario to realize that the glaciers which covered the country during the Glacial period did not carry away all the soft, oxidized, or residual material, and that such material may still be found in many places under a covering of boulder clay."

There is to be inaugurated in June in Australia an aerial mail service, which will encircle the Commonwealth. The points of call will include many localities at present difficult of access. Broken Hill and Kalgoorlie will be among the stations. The climate of Australia is ideal for aerial navigation.

# LETTERS FROM SOUTH LORRAIN

I PAST AND PRESENT

As is often to be expected, there has been argument and cavilling about the degree of credit due the mining geologist whose diagnosis and prognosis were the immediate cause of the revival of mining in South Lorrain. Much of this argument and cavilling was, so to say, sired by ignorance out of that fecund dam, prejudice. And most of it has been in exceeding bad taste. He who takes the pains to visit Silver Centre, South Lorrain, and observe and learn at first-hand, will find that there is no room for argument. The recorded facts are indisputable.

Silver ore was first discovered in South Lorrain on the claim now known as the Keeley, in December, 1907, by Keeley, Wood, and José, three well known prospectors. The claim had been originally snow-staked by the Shone brothers of Haileybury. The discovery consisted of rich specimens of wire silver and argentite, much weathered and oxidized. No general prospecting was done, however, until the summer of 1908.

The brief and fitful life of South Lorrain during the following few years is a matter of history. The Farmers' Bank provided cash to the amount of \$1,000,000 in exchange for perfectly worthless bonds. This sum was used in paying for the two claims, Keeley and Beaver Lake, that constitute the present Keeley property, and in equipping and operating the mine for slightly more than two years, when it was closed down, apparently for all time. A neighboring property, the Wetlauffer, had produced some bonanza ore during this period. It is reported that one vein produced no less than 3,000,000 ounces. The Wetlauffer company obtained an option on the Keeley in 1911 and did some work on it during the winter of 1911-12. Meeting with no encouragement whatever, the work was stopped and the option given up after a few months of underground exploration.

In the autumn of 1912 Dr. J. Mackintosh Bell first visited South Lorrain. Except for the last flicker of activity at the Wetlauffer, the camp was dead.

Dr. Bell's co-ordination of geological and topographical data gave him what he took rightly to be the key of the situation as regards ore deposition. Early in the year 1913 his London principals consented, on his strong recommendation, to take an option on the Keeley and to provide money for re-opening, equipping, and operating the mine. Work was carried on until the outbreak of war. Dr. Bell, after active service in France and Siberia, returned to Canada. Very little development had been done in his absence. The option on the property was finally implemented in the year 1918. By this time a considerable amount of milling ore had been developed and the erection of a mill was decided upon. Again Dr. Bell's London principals furnished the money. The abnormally high cost of skilled labour, together with other adverse circumstances, made it impossible to keep expenditure within estimated limits. Once more London came to the rescue. Not until the autumn of 1921, eight years after Dr. Bell's first visit to the camp, did the first proportionate reward for these years of patient waiting come. It came in the form of bonanza ore-shoots in the now famous Woods' vein. On the 3rd and 5th levels (a lean zone intervening) spectacularly rich ore-shoots were brought in

as the result of systematic underground prospecting. It was not long before there was enough ore developed and indicated to assure the mine a profitable (even if brief) life. Further development proved the persistence of these shoots to the 7th level and indicated their probable continuance below that level. Other veins were cut and other rich shoots opened. At the present time (I write this without official sanction and in a manner directly at variance with the meticulously restrained policy of the Keeley directorate) the ore reserves of the Keeley, to the 7th level, represent enough milling ore to supply the mill, the capacity of which is presently to be doubled, bringing it up to 150 tons per day, for several years, regardless of current and future development. There is also enough shipping ore in the stopes to maintain continuous shipments of high-grade for an equally long period. It is significant that the ore reserves are now very much larger than when the mill started, and that returns have consistently exceeded estimates. The silver content of the ore reserves at the close of 1921 was double that of the previous year. Similarly the estimated reserves at the close of the year 1922 represented twice as much silver as did these of 1921.

\* \* \*

The Keeley is now a success, as is also its neighbor, the Haileybury Frontier, owned by the Mining Corporation. As regards the constructive faith and clean spirit of intelligent venture shown by the English directorate of the Keeley in giving their continued financial support to an enterprise based wholly upon geological deductions, I can think of no parallel case where Canadian capital has been involved. Canadian capital demands something more tangible, and demands, also, a larger *quid pro quo*.

I doubt if more than two or three mining men in the North and otherwheres believed until quite recently that in contrast to the ore deposits of Cobalt, the Lorrain in general, and the Keeley mine in particular, were regarded not as merely moribund, but as dead and finally interred. Even the easily substantiable statement that in contrast to the ore deposits of Cobalt, the Keeley deposits are in places intensely oxidised was received with scepticism. In short, South Lorrain was extinct and better forgotten.

It took something more than ordinary courage to persevere against the obstacles that nature had provided. Perhaps the jibes of the scornful acted as a stimulant. In any case, the resuscitators of the Keeley may now inscribe Q.E.D. after the expectations that Dr. Bell held out to them eight years ago.

\* \* \*

The one regrettable feature of the revival in South Lorrain is the cheap and nasty advertising that certain promoters, interested in properties near the Keeley and Frontier mines, are now spreading broadcast over the land. In a later letter I shall refer to one, perhaps two or three, of these. The Keeley and Frontier are being operated on their merits, soundly and carefully. It is lamentable that their names should be prostituted by irresponsible outsiders. The good character of the camp must and shall be preserved.

J. C. MURRAY

# British Columbia's Heritage of Minerals

MINISTER OF MINES ADDRESSES NORTHWEST  
MINING CONVENTION IN SPOKANE.

On May 24th, Hon. Wm. Sloan, Minister of Mines for British Columbia, addressed the Northwest Mining Convention, held this year in Spokane. His address, in part, follows:

From me, no doubt, you will expect to hear something about mining, more particularly in my own province of British Columbia. I can say, without further preface, that never since I assumed office as Minister of Mines seven years ago have conditions been better or the outlook brighter. Now that is saying a great deal, for it will be remembered that the years 1916, 1917 and 1918 were big years in point of production. The value per annum of British Columbia's output ranged round the forty million mark. These were the years of the Great War. Demand for the product of the mine the world over was insistent, prices were high, everywhere was inflation. It was an unnatural condition, but it is generally conceded that those who had "the goods" benefited as far as profits are concerned. But it was a boom that was bound to be followed by more or less depressing reaction and that reaction came. I believe it has come and gone. The present conditions in the Province to the north of you point to a revival, not of the unhealthy prosperity of the war days, but towards progress and prosperity built upon the solid foundation of developed resources and the normal demands of the markets of the world.

## Eastern Capital Required for Western Development

Our production in terms of money for 1922 was not as great as it was in the big years to which I have referred, but it was approximately 25 percent greater than in the previous year,—over thirty-five million as compared with twenty-eight million. These figures illustrate the fact that I should like to make the keynote of my remarks—that we are on the "up grade." But it is not alone the fact that the Province of British Columbia has made an advance upon which I am depending. It is the fact that from all quarters there come assurances that we may go forward with confidence. We need capital in this western country and that capital, the "sinews of war" to mining, comes from the east. There was a time when Russian investments, Asiatic enterprises, middle European projects, and so forth were launched in the money markets of the world with success. It is unnecessary for me to say that a Russian bond issue in London or New York to-day would not receive much consideration; nor is it probable that requests for funds from any of the other countries I have mentioned would be more welcome. Where is the world going to place its reserves that they may be given a fair chance to multiply? I suggest that it does not require much insight to give the answer. The capitalists are turning more and more to western America and to those few other countries where today there appears to be stable government.

All the information I have received from London confirms what I have said, and I believe that it is true also of the great money market of New York. The people with funds are looking west. We have the resources requiring development; they have the means to assist in that vitally important work. What we have to do is to be good, reliable sales agents, displaying our wares without misrepresentation, and securing for their exploitation what their

worth seems to merit. If we adopt this as a principle in the prosperous days I see ahead, there is no doubt that the Northwest will be opened up in the next decade on a scale unprecedented in any previous period, to the lasting benefit both of ourselves and of those who will follow us.

## Reasons for Hopeful View of the Future

To revert to conditions in British Columbia, there are several reasons for my optimism of today. When I review the situation broadly it seems to me that we are justified in taking an optimistic view. One of these reasons is the wonderful promise of that newly opened up mining district, the Portland Canal of Northwestern British Columbia. Another is the marked advance that has been made by one of our greatest mining corporations in solving the metallurgical problem of the economic treatment of the complex ores of the Kootenays. The third, and perhaps the most important of all, is that the copper market now seems healthy, and that means everything to British Columbia mining. If this condition persists there can be no doubt whatever but that our production will go forward with a bound in 1923. This is all the better assured by the fact that the Dominion Government has offered a bounty of 1 1-2 cents a pound on copper in bars and rods manufactured in Canada from Canadian ores. Although the matter is not of special interest on this side of the line, I mention it only to explain that I join with operators and mining men of our Province in my approval of the policy of the Federal Administration in this matter.

## Copper

While on the subject of copper let me say that British Columbia production in 1922 dropped to about thirty-two and a half million pounds as compared to the normal of approximately forty million pounds. That it is possible to show an increase on the value of the whole mineral production in the face of this decline, it seems to me, will appeal to all as rather creditable. The reason for this unfavorable showing is known to most of you. Primarily it was market conditions, and under the circumstances it is very much to the credit of one of our greatest copper producers operating in the northwest, that they were able to continue work by means of lowering their costs. Another large producing company, situated in the southwest, was assailed by misfortune. Its plant was completely destroyed by fire and flood. To this corporation is due congratulation on the spirit with which it grappled its problems. This concern has also opened up important new ore reserves, its plant has been renewed on a larger scale and with a design of more modern type, and it has now again entered the field of production. Having these facts in mind it would appear reasonable that I should be most optimistic as to the results this year.

This, however, is not everything. In the north the company to which I have referred is extending its mineral holdings and adding to its plant. Not only that, but it is understood to be acquiring important, and hitherto inactive properties on Copper Mountain with a view to immediate operation. In addition we have the new concentrating mill nearing completion at Kimberley, and the promise it gives

of releasing the Trail concentrator for the use of the ores of Rossland. Under these circumstances it is not unreasonable that we should look forward to the future with confidence.

### Lead and Zinc

Consider lead and zinc. It will be noted that the Province has been advancing in production year by year. British Columbia was responsible for a production of over thirty-nine million pounds of lead in 1920, over forty-one million pounds in 1921, and of over sixty-seven million pounds in 1922. Zinc has been going ahead in the same way. In 1920 there was produced over forty-seven million pounds, in 1921 over forty-nine million pounds, and in 1922 over fifty-seven million pounds. These are interesting and significant figures to us. They speak well for the enterprise and the progressive spirit that dominates the greatest mining corporation of the eastern interior of the Province. The indications are that the mining of the silver-lead-zinc ores of the Kootenays will continue on an ever increasing scale, that metallurgical science will continue to improve the methods of treating these ores, and as improvements are effected the independent operators should be given the benefit to an increasing extent.

### Coal

It is possible that not so many of my hearers are interested in coal mining and yet I must refer briefly at this point to conditions in British Columbia. This industry has not been going ahead as it should, having been practically at a standstill in point of production for the past thirteen years. In 1910 it reached the peak of 2,800,000 tons and in 1922 it was 2,511,843 tons. The years between show fluctuations that on two occasions have taken the total below the two million mark. Our coal resources are sufficiently great to warrant much more extensive development and output. The markets, however, are not steady. At present, for instance, we are suffering from a distinct slackness of trade that has been reflected in the production of the months of April and May in the Vancouver Island, the Interior and the Crow's Nest fields. This means that men are thrown out of work and the coal mining centres are made to feel the pinch of hard times. I do not know whether you have the same problems on this side of the line, but personally I have reached the conclusion that some action on the part of our Government is necessary in order to relieve the industry from the disabilities at present existing.

### Iron and Steel

In this connection I may say that the coal industry would be stabilized and assisted to a large extent if an iron and steel industry were launched in the Northwest. The possibilities of this are not being overlooked in British Columbia. We have large magnetite and hematite deposits, the former both on the coast and in the interior, the latter for the most part in the interior. Dr. Young of the Canadian Geological Survey is now conducting a thorough survey of these deposits under the joint auspices of the Dominion and Provincial Departments of Mines. He will be in the field again this year. His report, when it is issued, will give accurate information, commercially speaking, as to the iron ore resources of the Province. I am very hopeful that it will lead to the immediate investment of the capital necessary to start the industry in question. When it does it will mean not only stability to coal mining, but a stimulus to our general prosperity both in British Columbia and throughout the whole of the Northwest.

### The Pioneers

The Province I represent is large in area and small,

proportionately, in population. We have districts that have made mining history and continue to do so. I note that the City of Nelson recently received the rifle and the pick that the late Eli Carpenter, discoverer of the Slocan used in his explorations of the wildernesses of the interior country. It is gratifying to find that citizens of Nelson, and of other British Columbia centres, are alive to the importance of preserving souvenirs with such historic associations, for it is upon the indomitable spirit of such pioneers that the development of the mining camps of the Northwest has been based. There are many other pioneers identified with the Kootenays in the early days, with the Cariboo, and with the placer fields and lode camps of the far north, whose memories are deservedly being preserved for posterity.

What can be accomplished now in building upon the work of those pioneers has been strikingly illustrated by the phenomenal success of the Premier Gold Mining Co., in the Portland Canal District. To declare dividends of some three and a half million dollars in little over two years speaks well for the mineral wealth of our Province and its possibilities. Other properties of marked promise are being opened up in this District and it is not all improbable that more than one first-class mine will be the result of the intensive prospecting and development now in progress in that locality.

### Hudson Bay Mountain

It is noteworthy that properties on Hudson Bay Mountain, actively developed during 1922, have given most satisfactory results. In one instance at least, what was only a few months ago but a prospect is rapidly developing into a mine, having already shipped quantities of high-grade ore. The zone is reported to be well mineralized and it is not improbable that other properties will be opened up in the same region this season. It is certain that there will be much prospecting in the locality and there is no doubt that it is justified. In the Cariboo the placer discovery at Cedar Creek may be said to be a notable event from a British Columbia standpoint, for the recovery in one brief season of \$125,000 in gold dust by the primitive means of rockers alone is no mean achievement. It has served to direct attention to the great northern interior and I have confidence that the result will be greater activity in the way of hydraulicking and dredging operations as well as more prospecting. The result should be an increased production of placer gold this year.

### Vancouver Island

On Vancouver Island the mineral prospects are good. In addition to coal mining there are a number of large ore-bodies under development. One of these is known as the "Sunloch," Jordan River, on the southwest coast. The work done here has disclosed a large body of copper-bearing ore which, without a question, will be exploited on a large scale. The same applies to the Old Sport Group of claims on the west coast of the Island.

Of the Kootenays, Mr. A. C. Langley, the resident mining engineer, is here to speak in detail. It is sufficient for me to say that the prospects are very encouraging, that this section is only at the beginning as far as development is concerned, and that here, as everywhere else in the Province, will be welcomed the co-operation in person or in capital of our immediate friends south of the 49th parallel.

### Protection Against Fraud

I note there has been considerable controversy upon the question of "Blue Sky" legislation and the conditions governing investments in British Columbia. I may say that,

with regard to mining, while we have no strict and recognized "Blue Sky" Law, we endeavour as far as possible to protect the investor against fraud. The difficulties of this are well recognized. Nevertheless we are determined, as far as it is within our power, to assure for the investor a fair "run for his money," so to speak. The Mineral Survey and Development Act, which divides our Province into six mineral survey districts, each under the direct supervision of a well qualified mining engineer employed by the Government, contains a clause requiring that district mining engineers be supplied with copies of all prospectuses or other publicity matter issued by promoters and mining companies operating in this Province. If these publications are found to contain representations not in accord with the facts as found by the district engineer after investigation, the latter must notify the Minister of Mines. The Minister then has the power, under privilege, to publish the truth. This menace of exposure has been found to work out very satisfactorily so far. It certainly is a potent deterrent to the fraudulently inclined. Furthermore, we do not want and will not tolerate a revival of the conditions that prevailed a quarter of a century ago, which retarded legitimate mining to an extent from which we are only now recovering. We also provide for the payment every two weeks of men employed on properties under bond or lease, and require that security be advanced for the payment of a fortnight's wages for those employed. This is for the protection of the workmen. Our whole object in these measures, as I have said, is to see that money invested in a mining property is spent on that property and not in stock manipulation. In the main we think that British Columbia's Mineral Laws are based on sound principles. Certainly they have worked out smoothly and satisfactorily thus far, and for that reason we have not permitted constant tampering and interference with them. Our policy is to promote stability and to give to the mining man an assurance that no vital changes will be made, so that he knows where he stands at all times. I have found usually that this is appreciated and endorsed as a good policy.

### Prospecting Needed

More than anything else we need prospecting. Without the prospector's work there is small hope of our minerals being exploited. The deposits, of course, must first be found. It is gratifying, therefore, to note the recent movement manifested in the organization of Prospectors' Associations. These Associations can do, and I believe are doing, much good. They are being assisted by our district mining engineers, whose lectures, delivered during the winter season in all parts of the Province, are having the effect of stirring up interest in mining and giving the prospector good practical information and advice. The Government, too, has been spending many thousands of dollars in opening up the inaccessible parts to the searcher for minerals as well as in affording transportation conveniences to the struggling operator. We have built hundreds of miles of roads and trails and have constructed and maintained many bridges in the course of carrying out the policy of aiding the mining men in the work, fraught with so many difficulties and problems, of winning the minerals from the far distant corners of the Province. We appreciate that in doing this we are performing no more than a duty, the benefits and the returns from which may be depended upon to be realized in the near future, if not in the immediate future. The work must go on. It is possible that the prospector of a few years hence will be further aided by aerial navigation. This science is making progress, and it does not require much stretch of imagination to see the prospector being conveyed through the air with his outfit to the particular district he has selected for his

work. In fact the method already has been adopted in small measure out of the town of Hazelton, British Columbia, and before long it will be possible for the big business man of New York, Chicago, Toronto or Montreal to leave his office and within a few days, by train and aeroplane, to be in the frontier wildernesses of British Columbia inspecting a prospect and incidentally enjoying the big game hunting of the country for which our province is noted.

Decidedly we are on the "up grade." Mining men of the West have every reason for confident optimism. That is the way we feel in British Columbia. It is the sentiment that should pervade this Convention. It is the feeling that we all should carry away with us. If we grasp and hold to that idea it will be of material assistance to us as we go hence to grapple with the many problems that will arise in the course of the year's activities.

## LETTERS FROM READERS

### Forest Fires

To the Editor,

Canadian Mining Journal.

Sir:

In the April Number of the *Canadian Forestry Magazine*, the leading article dealt with a statement made by Mr. John Rudolphus Booth, of Ottawa, reflecting rather strongly upon the prospector. I have been expecting to see more indignant replies made to the statements in the article.

The article says in part:

"It does account for the swarm of prospectors' fires," he replied with sudden energy. "Take for example our Montreal River Limit, 1,700 square miles, that we bought a few years ago for \$300,000 in open competition. That, of course, is not the final payment, for ground rent, fire taxes, and cutting dues must be added. That country was absolutely green at the time we bought. Spruce stood as thick almost as corn stalks — a beautiful country, as fine as ever I saw. I could not find traces of a single fire over the whole extent. Well, we had it only a short time when it was opened to prospectors, opened, mind you, without evidence of a solitary mineral showing on any part of it, no preliminary survey of geologists. To this day, not a mine nor a real prospect has been uncovered on that 1,700 miles, but," Mr. Booth's eyes flashed a world of feeling, "a horde of irresponsible men seeking non-existent mines have destroyed from one-third to half of that country. They have ruined as much timber as would have kept our Ottawa mills running for twenty-five years and the end of their devastation is not yet. The lumberman made the roads, the lumberman paid for the timber, but the Government opened wide the doors to the prospector whose first incentive is to spread fire and clear off the surface of the rocks. I know the history of some of our forests for seventy-five years and I am frank to say that I believe every dollar's worth of mineral taken from forested land has cost the country a hundred dollars in destroyed timber. Why not make a business-like calculation of the price we pay for letting loose the prospector on the country's fast-depleting stock of timber? The showing would make us rub our eyes." etc.

There are several things in the above extract that one would like to comment upon: for instance, why should such a beautiful country with spruce as thick as corn

stake is sold at the rate of about \$175.00 per square mile, to J. R. Booth or anyone else, especially as not one stick of the timber on the seventeen hundred square miles was to be manufactured within hundreds of miles of where it grew?

Then Mr. Booth says "a horde of irresponsible men seeking non-existent mines have destroyed from one-third to one-half of that country." The Government exacted from every prospector that went on the country that Mr. Booth speaks of, a yearly fee of ten dollars for the right to prospect upon that so-called forest reserve, and if I am not mistaken, the Government received at least one hundred thousand dollars from these permits alone, and altogether from fees taken from prospectors on that same territory a good deal more money than Mr. Booth paid for the whole concession.

I wish to contradict the statement made by Mr. Booth that the territory in question was burned by prospectors. It is true, and no one will deny it, that there are some prospectors, as there are a great many lumbermen, careless about fire and it is quite possible that some fires have been started by prospectors; but the fire that destroyed the greater part of the burned territory that Mr. Booth speaks of was started by fire rangers in 1912-13. The fire rangers were camped at Alexandra Lake and I am sure that Mr. Booth's office has record of the fact that the fire started then, which burnt over two or three hundred square miles of the Forest Reserve, was started by the fire rangers in question, who burned their own camp, the fire then spreading over a large extent of the area. There were no large fires on the forest reserve set by prospectors.

Now as to the "non-existent mines". It is true there have not been many mines found in that territory yet that have paid dividends, but there are several that have procured a large amount of silver, and the Miller Lake-O'Brien, which is in the middle of the territory in question, has produced about six million ounces alone up to date, and there are others that will in time produce millions of dollars.

The whole strain running through Mr. Booth's remarks shows the lumbering idea — everything for the lumberman. The greatest trouble in his mind in regard to the devastation of the forest was that this timber that was burned would have kept the Ottawa mills running for twenty-five years. The great fire I have mentioned that was started at Alexandra Lake would probably not have spread far had it not been for the vast amount of debris with which the forest was filled from the lumbering operations.

Any prospector knows that a forest fire does not clear off the ground for prospecting. The first fire makes it ten times harder to prospect than it was before, and even a second fire generally does not improve it any. It takes, as a rule, three or four fires before the ground is cleared so that it can be of any benefit to the prospector.

I have a recollection of six townships on the Sturgeon River owned by Mr. Booth, where there was no prospecting, and they were more completely burned, and in a much shorter time following the lumbering operations, than any ground on the Montreal River district.

The statement in the article above quoted that "every dollar's worth of minerals taken from the forest or land has cost the country a hundred dollars" is absolute nonsense. The mines of Temiskaming District have produced hundreds of millions of dollars. The timber in the same district is only worth a fraction of the value that has already come from the mines, and the mines have only started.

I have a great respect for Mr. Booth and I have known him for a long time. No one doubts his probity, but like every other lumberman, he is obsessed with the idea that lumber is the only thing that should be considered.

The class of timber Mr. Booth is cutting on the Montreal River can be renewed, in 30 or 40 years without much expense; a re-forestation policy will be necessary to renew it in some sections, in others it grows naturally.

H. E. McKee,  
Cobalt, Ont.

## BOOK REVIEWS

WAVELENGTH TABLES FOR SPECTRUM ANALYSIS, Compiled by F. Twyman. Adam Hilger, Ltd., 75A Camden Road, London, N. W. I. — 106 pages — 7s. 9d. post free.

Analysis by means of the spectroscope is of growing importance as an adjunct to industry. For this purpose two sets of tables are required, one giving the wavelengths of certain radiations reproducible in the laboratory, to be used as datum points, and the other giving the wavelengths characteristic of the various elements. Both sets of tables, with adequate explanation, are given by Mr. Twyman. Messrs. Adam Hilger specialize in optical apparatus, and the present volume rounds out their facilities for spectrum analysis.

THE ENGINEERING OF EXCAVATION, By George B. Massey. — John Wiley and Sons, New York, and Renouf Publishing Company, Montreal. — 376 pages, illustrated.

The problems of excavation are common to many branches of engineering and are treated of incidentally in numerous text-books and other volumes. Here, however, the author has drawn upon an experience of more than twenty years specialized in excavation work to give the subject comprehensive treatment. The result is one of the growing number of special treatises useful for reference. The author states specifically that his object is to help the engineer to choose the most suitable machinery for the work he has in hand.

Commencing with revolving shovels, the land types of excavators are described, the principles upon which they operate, and their special applications. A number of the newer types mounted upon caterpillars are included. Ditchers and "dry land dredges" are treated of fully. The various accessories such as buckets, engines, pumps, drills and the means of transportation, are treated separately. A chapter is devoted to hydraulic and hydraulic lifts. Dredges for the purposes of excavation and for placer mining are described comprehensively. While this book could not be used effectively as a text for teaching, and while its nature might make it difficult of comprehension to the young engineer, it will form a very useful work of reference for the engineer with whom excavation is an occasional, but necessary, employment.

The annual report of the State Mines, South Africa, for 1922 discloses the following facts: Over 8,000 natives are employed: 600,874 ounces of gold was won from 1,357,000 tons of ore, the working profit per ton being 18s. 10.8d. The sorting of waste from ore has increased the profit materially. The ore reserves are 10,324,000 tons.

# British Columbia Division, C. I. M. M.

REPORT OF THE SECRETARY FOR THE FISCAL  
YEAR ENDING APRIL 30th, 1923.

If the success of the largely attended meetings held under the auspices of the Division during the past year can be taken as a criterion of the interest of the members in the Division and its work, there is every reason for congratulation on this score. Indication of general interest has been manifest, moreover, in the proportionately large number of replies received to the questionnaires issued by the Secretary on various matters from time to time during the period under review. It must be admitted, however, that except in localities in immediate touch with Divisional Headquarters, such as Vancouver and the coal mining centres of Vancouver Island, and where conditions are exceptionally favourable for frequent and representative gatherings, apathy has still to be combatted. This was evidenced in particular at a meeting between members of the Executive Committee and Kootenay members following the International Mining Convention in Nelson in July last, when a proposal to organize a Kootenay Section with Branches in the Slocan and in East Kootenay, having in view the holding of regular annual meetings in the Interior as well as on the Coast, was rejected on the grounds that it would be impossible to stimulate interest sufficiently to maintain such an organization. But then, it should be noted, mining in the Kootenays was in a very depressed state, and with the improvement in the situation that has since taken place and the more optimistic feeling generally that has been engendered, it is hoped the inertia that prevented the entertainment of the project of a Kootenay section will be overcome. As a step towards that end it has been arranged that a General Divisional Meeting will be held in Trail next October, and Kootenay members have been urged in the interim to do their part to ensure a representative attendance, and incidentally to take advantage of the occasion to increase the membership in their section. Our problem in British Columbia as a Division, is the same problem that confronts the Institute as a whole—one of geography, and also of diversity of interest. Our mining centres are widely distributed and are separated by considerable distances. To travel from Stewart or Anyox, from Fernie or Kimberley, or even Rossland or Nelson to Vancouver, or from Vancouver to any of these points, is a lengthy procedure, occupying from three or four days to a week. It is likewise expensive. These are deterrents to communal intercourse and without such intercourse, without the establishment of a strong "esprit de corps," and without the binding power of a common and definite purpose or motive, the creation in outlying districts of a widespread interest in Institute affairs in any degree constant or permanent, has been found difficult.

## Establishment of Branches

In some instances the problem may be partly solved by the establishment of branches or "locals;" but the continued success or usefulness of a branch is dependent on several factors, the absence of any one of which is fatal. Primarily and fundamentally the success of a Branch depends on leadership. A Chairman or Secretary has to be found who is a public spirited and an untiring enthusiast with the capability of enthusing others. Such men are unhappily not common. It is almost equally as essential that such a Branch should afford an opportunity, not otherwise readily presented, for members to meet and inter-

change ideas on matters of direct and common interest to them.

The ideal condition is a camp of a number of mines of a similar character within easy reach of a common centre, and where, for example, differing methods of practice provide material for effective comparisons. A Branch, the members of which are mostly employees of one large corporation, and who in consequence are regularly thrown into one another's company, has less incentive to exist, although, in the case of the Anyox Branch, inspiring leadership was enough to overcome the handicap.

Meanwhile there appears to be excellent opportunity for the establishment of an active Branch at Stewart, or in the Portland Canal district, and preliminary steps have already been taken to that end.

The foregoing recital is sufficient to indicate the nature of the problems facing this Division, and a sustained effort has been made during the past year to cope with them.

## Division and Branch Meetings

The meetings held during the year by the Division, or under its auspices, have included the General Meeting in Vancouver in February 1922, the Western Meeting of the Institute in Vancouver in November of that year, and Branch Meetings at Rossland, Vancouver, Ladysmith, Nanaimo and Cumberland. Except during the three summer months, the Vancouver Branch met regularly at monthly luncheons throughout the year. Some of these luncheons were held in conjunction with the Mining Bureau of the Vancouver Board of Trade, and the B. C. Chamber of Mines.

The meetings have in every instance been characterized by large attendances, and by a keen interest displayed in the proceedings. The registered attendance at the Annual General Meeting of the Division was approximately three hundred, and no less a number were present at the General Western Meeting of the Institute, and included representatives from the membership in every Province in the Dominion, as well as a number of distinguished mining engineers from the United States.

It should perhaps be noted that the arrangements for the Western Meeting, including the securing of papers, were undertaken and successfully carried out by a Committee of Vancouver members and that a sufficient sum of money was collected locally to defray all the expenses, which otherwise would have been a charge on the parent body.

Concerning the Branch Meetings, a specially satisfactory feature has been the establishment of sympathetic and friendly relationships between members engaged in coal mining on Vancouver Island and those associated with metal mining on the Mainland as a result of the arrangements for frequent joint meetings between the Vancouver Island Branch and the Vancouver Branch. At these meetings the Vancouver Island Branch has acted as host, in which capacity their kind hospitality and ability as entertainers has been most amply demonstrated.

## The Year's Work

Of public questions affecting mining with which the Division has concerned itself in the past year three may be mentioned, the desirability of the report on amendments

to the "Professional Engineers Act," provision to bring about the standardization of examinations throughout Canada of candidates for certificates of competency in connection with coal mine management, with a view to establishing a Dominion-wide validity for such certificates; and the desirability of recommending an increased tax on unworked Crown Granted mineral claims as a means of discouraging the speculative holding of mineral areas.

As stated in last year's report of the work of the Division, the views of the members on the "Professional Engineers Act" was invited by the issue of a questionnaire, the replies to which, indicating a considerable divergence of opinion, were submitted to a special committee, under the chairmanship of Col. Guy H. Kirkpatrick, appointed by the Divisional Executive to study the question and report their conclusions thereon. After holding several meetings this Committee presented a report intimating that in their judgment it would be inadvisable "to interfere with the Act at the present time or to amend it for at least a year or two," on the grounds that "so far it has not had time to have any effect one way or another," and, it is added, if later on it appears that any amendment would be beneficial, action can be taken by the Division accordingly. The Committee note also that as legislation of a similar character has either been adopted or is being introduced in other Provinces, that it would seem to be desirable for the Institute to endeavour to bring about the standardization of such legislation to the end that registration under the Act of one Province would carry with it the privilege of practising in any other Province without further formality. A reciprocal arrangement on like lines with the various States where similar Acts are in force is also recommended.

Measures to bring about the standardization of examinations for coal mine managers' certificates in Canada, preliminary to an inter-Provincial recognition of such certificates, has been referred to the General Council of the Institute for action, and is now receiving the attention of that body.

The desirability of recommending the imposition of a higher tax on unworked Crown Granted Mineral Claims has been the subject of correspondence between the Division and the Prospectors' Associations, which at present are unfavourable to the project in the belief that it is not in the interests of prospectors. As the essential purpose of the proposal is to benefit the legitimate prospector by forcing the release for exploration of considerable areas now held by speculators in the more accessible districts, it is hoped that as a result of further argument the support of these Associations will be secured.

### The Iron Ore Survey

Periodical meetings of the Administrative Committee were held during the year, at which action in the name of the Division was authorized on several matters of public importance. Thus the Division submitted a recommendation to the Canadian Department of Mines urging that a detailed geological survey of the iron deposits of the Province be at once undertaken, and other means adopted in co-operation with the Provincial Department of Mines to determine authoritatively the potential value and extent of these resources. The grounds for this recommendation were that although for many years past there has been much talk of the establishment of an iron and steel industry in this Province, the evidence of the existence of extensive bodies of merchantable iron in quantity is not sufficiently conclusive, and it was believed that in order to create genuine enquiry concerning the possibilities of utilizing commercially these resources, it was desirable to establish the basal fact that the resources existed. It is

gratifying to state that the Department of Mines promptly acted on the recommendation, which was most heartily endorsed by the Hon. W. Sloan, and it was agreed that a detailed survey of all known iron occurrences in the Provinces should be made by a geologist who has special experience in this class of investigation, and who subsequently spent the summer in the field.

Acting in consort with the parent body, the Division communicated with the Prime Minister, the Rt. Hon. MacKenzie King, upon the return of the present Government to power, strongly advocating that in the selection of a Minister to assume direction of the Dominion Department of Mines, due consideration be given to his qualifications effectively to serve the mining industry in this important capacity. The subsequent appointment of the Hon. Charles Stewart as Minister of Mines has given general satisfaction.

The Administrative Committee has also communicated freely with headquarters on Institute affairs, and its views have invariably received courteous consideration.

Under the arrangement, to which reference was made in the Division's report of last year, by which the Granby Mining, Smelting and Power Co. and the Crow's Nest Pass Coal Co. were good enough to agree to provide "instructional" employment, for a period of two years, to graduates in mining of the University of British Columbia, two graduates of the University were recommended for, and were duly given employment at, respectively, Anyox and Fernie, during the year.

In conclusion, it is but fitting that reference should be made to the great loss the Institute in general and the Division in particular has sustained in the death, in December last, of Mr. J. D. MacKenzie who, for two successive years was a member of the Administrative Committee of the Division. The enthusiasm, energy, and devotion that he brought to bear in this capacity were a constant inspiration to his colleagues; and the success of the meetings up to the time of his death, and the strong revival of interest in the Institute's work in British Columbia during the past two years, may be attributed very largely to him.

H. Mortimer-Lamb, Secretary.

### RATE OF DISTILLATION AFFECTS QUALITY OF SHALE OILS

Studies made at the oil shale laboratory of the Bureau of Mines, Boulder, Colorado, indicate that the changes in the quality of crude shale oils produced by varying the rate of distillation, may be due to (a) the temperature at which the decomposition took place, and (b) the extent to which the thermal reaction progressed. The temperature studies show conclusively that the oils produced in the slow rates of distillation are actually produced at much lower temperatures than the oils formed by rapid distillation.

The practical limits to which controlled cracking within the retort may be carried are not yet determined, but since time or temperature are such important factors in the production of good crude shale oils, it should be feasible in commercial retort design to balance size of retort and heating surface, rate of heat supply to the shale, size of shale particles, and rate of throughput, so that the most desirable rate of distillation, and subsequent thermal reactions, can be obtained. Thus, it should be possible to govern, within fairly wide limits, the qualities of the crude oils obtained, and thereby to produce crude oils of the most desirable properties for commercial needs.

## THE FREIGHT RATE ON ALBERTA COAL.

### Western Views of Sir Henry Thornton's offer

Coal mine operators and the business men of the Province of Alberta generally are disappointed that a greater reduction in freight rates has not been offered by Sir Henry Thornton, president of the Canadian National Railways, in order to permit the development of a market in Ontario for Alberta coals. One prominent Alberta operator is quoted as saying that the concession "will help some, but the rate of \$9.00 a ton is not low enough to open a market for continuous shipments during the summer months. For this we require a six dollar rate." It is pointed out that the present price at the pithead ranges from \$3.50 to 4.00 a ton and the delivery cost and retail profit from \$2.00 to \$2.50. With the \$9 freight added, the Toronto price would be from \$14.50 to \$15.00 a ton for Alberta coal, and this price, the Edmonton operators say, would not be sufficiently attractive to permit successful competition in the East, unless there is an abnormal situation such as might result from an Eastern strike and a consequent shortage.

J. Gouge, of the Western Canada Coal Operators' Association, states that the reduction does not go far enough. He says that it is hopeless to try to reach the Ontario market with a rate like that.

Commenting on Sir Henry's offer the *Edmonton Bulletin* says editorially:

"The \$12.70 rate on Alberta coal to Ontario is to be reduced to \$9.00 during the months of May, June and July for shipments in train-load lots. That is the announcement of Sir Henry Thornton to the chairman of the senate committee on fuel supply. That this announcement will be received with profound disappointment both in Alberta and Ontario goes without saying. High hopes were entertained in both the west and east that a rate enabling Alberta domestic coal to compete with the Pennsylvania anthracite in the province of Ontario would be granted.

"A nine dollar rate only during the months when the consumer does not want to buy coal cannot change the present situation for either producer or consumer in any material degree. It is quite possible that such a rate during the winter months after the close of navigation might be of some use. The demand for anthracite is outrunning the supply, the quality furnished the Canadian market is deteriorating, there are occasions of shortage, as during the greater part of last winter. When the consumer needs coal in winter the question of price is less important than the quality of the coal and the assurance that it will be supplied. The experiments recently made with Alberta coal in the eastern cities have proven its satisfactory character. But it is too much to expect that eastern consumers will stack up during early summer with Alberta coal at a price with which they know the Pennsylvania operator can compete if he will. During the months of January, February and March and from mid-December to mid-April, the householder needs coal for immediate use. If the Pennsylvania supply is short or the quality inferior the Ontario householder might buy Alberta coal at a price that would carry a nine dollar freight rate. But if he is asked to pay a nine dollar rate on coal that he won't need until four, five or six months hence, he can't be expected to do it.

"It is a little difficult to appreciate the application of Sir Henry's argument, that because of possible weather conditions the railway cannot haul at the nine dollar rate during the winter months. All other rates apply throughout the year, the railway taking chances on weather conditions. The fact is that the road has to be kept open in all weathers, and unless the circumstances are entirely exceptional the more traffic there is moving the easier it is to keep it moving.

"Sir Henry bespeaks the co-operation of coal operators and distributors with the railway company to 'achieve the common object'—presumably the use of Alberta domestic coal in Ontario. That is to say, he calls upon Alberta operators and Ontario dealers to cut costs and to forego profits in order to promote the Alberta-Ontario coal trade. This is very right and proper; but in this case as in many others it is 'After you, my dear Alphonse!' Operators and dealers will naturally ask: 'How much of a cut has the railway made in order to promote this very desirable trade?' An examination of the mileage and freight tariff sheets discloses the fact that the railway hauls wheat from Edmonton to Fort William at 26 cents per 100 pounds, or \$5.20 a ton; that figures out at 41.6 cents per ton per hundred miles, the rail distance being about 1,250 miles. It is practically 2,000 miles from Edmonton to Toronto. At the per ton mile rate charged on wheat to Fort William the rate on wheat to Toronto would be \$8.32 a ton, or 68 cents per ton less than the rate at which Sir Henry offers to haul coal under special conditions and as a special consideration. It will be observed that the rate quoted on wheat to Fort William is by the car, not by the train load, and is the same in mid-winter as in mid-summer. Also that the railways gave a very prompt and efficient service last fall, and both systems made more money than they had done for several years, showing that the rate was a winner, not a loser. The railway may or may not at present give the rate quoted between Fort William and Toronto, but if the rate makes money for them between Alberta points and Fort William it should equally be a money maker between Fort William and Toronto.

"It is an accepted principle in fixing railway rates that freight of low value per ton gets a lower rate than freight of a high value per ton. No. 2 northern wheat is quoted at Edmonton at 95 cents per bushel. At that rate a 40-ton car would carry a value in wheat of \$1,266.35. Domestic coal is worth, say, \$3.50 f.o.b. the mine, or \$140.00 per carload. Sir Henry's special concession on coal rates is that he proposes to charge \$27.20 per 40-ton car more on coal from Edmonton to Toronto (worth \$140 at Edmonton), than he is entitled to charge on a 40-ton car of wheat worth \$1,266 at Edmonton."

"Permissible explosives, mining equipment and apparatus approved prior to January 1, 1923," is the title of technical paper 333, just issued by the Bureau of Mines, Washington. It gives the brand names of 154 permissible explosives, and lists of approved appurtenances. The equipment and supplies listed consist of such things as breathing apparatus, coal cutting machines, electric drills, electric cap lamps, flame safety lamps, shot-firing units and storage-battery locomotives.

## ANGLO-AMERICAN FINANCIAL CO-OPERATION.

The dominant note of an outstanding address delivered to the Executive Council of the American Bankers' Association by Mr. F. C. Goodenough, the Chairman of Barclay's Bank, London, was that British and American interests are in many respects so essentially identical that some form of co-operation between the two countries in matters relating to Europe is ultimately inevitable, even though it may occasionally be delayed.

In considering this community of interests Mr. Goodenough instanced the question of foreign investments.

For some time past Britain has been an investing nation. The practice has not been adopted exclusively without reason, but the almost inevitable result of our position as an industrial nation, largely dependent upon our exports, for the maintenance of our own standards. We are thus faced with the alternatives of increasing our foreign investments and thus extending our exports, or of accepting payment at a risk of restricting exports and increasing our external imports. It has not so completely as Great Britain been forced to accept the first of these alternatives that it is certain that the accruing interests on our external investments was year by year re-invested and that, on balance, we took little or no immediate interest from our debtors on the capital loaned to them.

### Re-Investment Justified

At first sight it may appear to be difficult to justify such action, from the point of view of the prosperity of the country. But the reason of continued foreign investment has been gradually to develop fresh markets, to enlarge the productive capacity of the whole world, and to this extent to ensure a steady demand for our own goods, which more than anything else helped towards the expansion of our trade and maintained relatively steady employment for our people. It might be said that, although the whole world benefits from such a policy, it has been the one our immediate interest and we have certainly derived no direct benefit.

The United States is not so dependent upon foreign markets, but since the war her position has radically changed. Her economy is completely altered and her industrial organisation has been developed upon the basis of a favourable balance of trade. To this extent, her interests in foreign markets are similar to those of Great Britain. As creditor nations, neither country can remain indifferent to the conditions existing, if only for the reason that the value of their assets in foreign countries is affected. As exporting and creditor nations both countries are virtually compelled to invest largely abroad for, as Mr. Goodenough points out, "payments between nations can only be made in the following ways, that is to say, in goods, in services, in gold, or in securities. So far therefore as America is not prepared to accept payments in goods or services, or gold, she will of necessity follow the investments and maintaining such volume of trade as experience of Great Britain and other creditor nations and accept payment in securities.

"On the one hand, therefore, we continue to re-invest in whole or in part such payments as are made to her by foreign debtors, increasing her foreign in-

vestments and maintaining such a volume of trade as would afford her a surplus of visible exports. On the other hand she may avoid foreign investments, and as far as possible, accept payment in goods, or services, or gold, and in that case the position would be altered and there would be a surplus of visible imports."

### Co-operation Inevitable

These considerations are the basis of Mr. Goodenough's conclusion that ultimately some effective measure of financial co-operation will be forced upon the two countries, and he proceeds to develop his argument in its relation to the problem of European reconstruction and the difficult question of reparations. Co-operation does not entail united Governmental action, it has no necessary connection with politics, and it may be that it will take the form merely of a realization in each country that the question must and can be solved on strictly business lines.

Mr. Goodenough is reasonably optimistic of a settlement of what may be described as the political difficulties attending the question of reparations and he believes that it will not long be delayed. With this aspect of the question eliminated, the problem would become one of finance, the solution of which must be considered as a business proposition by investors in all countries. This section of his argument is summarized as follows:—

"I assume that an agreement will be reached in the matter of reparations, and I think that Great Britain and America, as the two great creditor countries of the World, can, by acting in co-operation upon commercial lines, carry the matter a long way towards a successful conclusion. I am, of course, aware that any proposition of this kind must be a sound business proposition, but it seems to me that the reconstruction of Europe and the general trade and prosperity of the World must depend upon finance, and if the people of Great Britain and America, as the creditor nations, are prepared to find it, they will at the same time serve their own individual and common interests.

### Germany to be Rescued

"The question then arises, are Great Britain and America, as a purely commercial proposition, likely to provide the necessary credit? I think that under certain circumstances, substantial sums would be provided by Great Britain. But will America do the same? She will decide what shall be her own policy, but I can unhesitatingly say that my personal opinion is that the commercial and investment interests of the United States will lead her to approach this problem from much the same point of view as Great Britain."

Mr. Goodenough believes that the initial sums required would not be excessive and that it would be possible for Germany to offer such security as would make her bonds acceptable in the investment market.

"I think German Reparation Bonds could be made attractive if the principle of the endorsed bond were accepted. I feel sure that to the investing public in Great Britain and America, in fact, throughout the world, a bond given by Germany, specifically secured by German assets and bearing also the endorsement of the recipient nation which had received it on ac-

count of reparations, would prove a marketable security, when once a reasonably satisfactory settlement is in sight."

There is one further point emphasized. It is not always realized how important a factor in establishing a business basis for a solution of the problem, the wide distribution of Reparation Bonds, among ordinary private investors, may be. By that means the ordinary business credit of the debtor country is indirectly, but none the less truly, concerned in the due fulfillment of the terms of the Government bonds. "Germany could not afford to default on a widely held bond issue, whatever she might do in regard to debts held directly by the Governments of her late enemies." Finally, there is the fact that Great Britain and America as great creditor and overseas trading nations would secure a substantial indirect benefit through taking part in these financial operations, inasmuch as they, by removing the present deadlock, would stimulate trade, promote peace and prosperity, and thus conserve and consolidate their overseas assets.

### The Effect of Debt Payments.

At the conclusion of his speech, Mr. Goodenough briefly considered the effect of the repayment of the British debt, more particularly from the point of view of its influence upon the possible restoration of a free gold market.

It is becoming probable that within a reasonable period the exchange value of sterling will once more return to its pre-war parity and, if the tendency of prices to rise in America continues, this return will be hastened.

But it does not necessarily follow that even with the pound at parity, London will be able to establish a free gold market. Much must depend upon the readjustments in foreign trade which may be entailed by the British payments to America. "The effect of the Fordney Tariff will probably be to discourage the shipment of such of our manufactured goods as may be likely to compete in America. It is probable, therefore, that these goods, instead of being shipped to the United States, will be shipped to British Colonies and other countries and will in effect be used to pay for shipments of goods which the United States will take from them." But increased exports to countries without adequate gold reserves would not enable this country to draw gold at need while our reserves would, with a free gold market, be subjected to depletion. Moreover, an effective gold standard demands a definite ratio between gold and currency and until "some definite, but steadily improving, minimum ratio is established between gold and currency, there is no certainty that a withdrawal of gold for export would, by restricting the currency in circulation, bring that contraction in credit and fall in prices which formerly served to check the outflow. It seems, therefore, that Great Britain, before establishing a free gold market, would have to adopt a ratio system, and even then would require to have experience as to whether the cross currents of international trade were being adjusted so as to enable the liability incurred towards America for payment of debt and the payments which will have to be made for food supplies and raw materials, to be met without an undue drain from America on gold reserves."

In the matter of gold reserves also, co-operation between America and Great Britain would undoubtedly benefit both countries and, however the various problems, both financial and industrial, are approached, it seems to be clear that the interests of America and Great Britain in foreign markets must be closely allied. — Monthly Review, Barclay's Bank.

### DETECTION OF CARBON MONOXIDE POISONING

Through investigations conducted by United States Government technologists, methods of detecting carbon monoxide, most insidious and deadly of poisonous gases, have been given. The Bureau of Mines has been conducting research work, with the result that means have been found by which it is possible to discover within three minutes the extent to which a person has been affected by carbon monoxide gas by dissolving in the blood. Formerly it took approximately from 24 to 48 hours before diagnosis could be made of such cases, either in hospitals or well-equipped laboratories with the services of a skilled organic chemist. The test is effected through a simple and inexpensive instrument that may be carried in the pocket and requires no special training for its operation.

Many human lives are expected to be saved by the general adoption of this means of determining gas poisoning, particularly in the mining industry. With this quick method of diagnosis it is possible promptly to institute the proper emergency treatment.

Carbon monoxide is the universal industrial poison gas and is found at mine explosions and fires, as a product of explosions, in the atmosphere round coke ovens, in coal gas, water gas, and producer-gas plants, as well as in the exhaust gases of automobile engines, from improperly constructed and operated kitchen gas ranges, and in smoke from burning buildings.

Because of the common occurrence of carbon monoxide poisoning, the new instrument for detecting the gas in the blood is expected to be in universal use among physicians in the near future. Symptoms of carbon monoxide poisoning consist of headache, dizziness, weakness in the legs, increased respiration, becoming irregular and depressed, finally resulting in collapse, unconsciousness and possibly death.

The symptoms, detection and treatment of carbon monoxide poisoning are described in an 11-page report, Serial No. 2476, just published by the Bureau of Mines, Washington, and available on request.

### INCREASED COPPER OUTPUT IN BELGIAN CONGO

The production of copper by the Union Minière du Haut Katanga in 1922 is estimated to reach about 42,000 metric tons, according to a circular issued by the Tanganyika Commission. The new blast furnace is being erected to produce 6,000 to 8,000 tons per annum, and will be working during 1923. Tests and designs are being prepared for the installation of a plant to produce 30,000 tons a year. This will form the first unit of the large plant that the Union Minière has in view.

# THE MINING DISTRICTS

BY THE JOURNAL'S CORRESPONDENTS.

## GOUDREAU

No. 1 shaft of the Goudreau Gold Mines Ltd. is near the 400-foot level. As soon as this level is reached a cross-cut will be run to tap the vein. Drifting on the vein at this level will be carried on to the same extent as on the 200-foot level. It is understood that plans for a mill will not be completed until conditions on the new level are known.

The Detroit-Goudreau Gold Development Co. have commenced drilling operations on their property south of Lochalsh Station. Several camps have been built and a fully equipped assay office erected. The present drilling program will consist of a row of holes cutting the shear zone at a depth of about 150 feet. Smith and Travers of Sudbury have the drilling contract.

Development work has been started on a property known as the "Lucky Eight," located about two miles east of the Magpie River in Township 29, Range 25. This property has been optioned from the owners by a syndicate under the leadership of G. L. Michael of Sault Ste. Marie.

Several promising properties are at present under option and everything points to a busy season in this camp north of Sault Ste. Marie.

## NORTHERN ONTARIO

**Cobalt** — The Continental Mines has made an important discovery of high-grade ore on the 925-foot level. In addition to high-grade, there is a considerable quantity of milling ore, and it looks as if this property were shortly to be numbered among the producers of the camp. The discovery is of considerable importance inasmuch as it is the greatest depth at which commercial ore has yet been found in the camp. Further north, on the same contact on the Violet property, La Rose has also run into high-grade at a depth of 635 feet in the new shaft. Arrangements have been made to mill the ore at the Mining Corporation's mill, and shipments have already commenced from the Violet and Princess properties.

The Beaver has commenced the work of unwatering the lower levels in order to permit development of the vein found at the 1,200 foot level. The old workings of the Beaver showed a very strong vein at this point, which carried a considerable amount of silver in places, and it is believed that closer to the contact the chances are excellent for striking ore. The unwatering will be done through the Temiskaming shaft in order not to interrupt the work being done on the Beaver. The lower levels of the Beaver and Temiskaming are connected, and the pumping can be done more advantageously through the Temiskaming shaft.

The Oxford-Cobalt is now drifting on a vein on the 150-foot level, in which at times erratic silver values have been found.

During the week ending May 18th, shipments from Cobalt consisted of 131,300 pounds of ore from the O'Brien and 84,100 pounds from the McKinley-Darragh.

McKinley-Darragh has commenced operation of its sand treatment plant, but the Dominion Reduction Company, which last year was treating Peterson Lake tailings, has decided not to operate this year.

**South Lorrain.** — Preparations are being made to commence work on the Lorrain Consolidated in South Lorrain. The property has one shaft down 240 feet. This will be continued to 350 feet. New equipment and supplies are being brought to the property and work should be commenced shortly.

The Hon. Howard Ferguson, at a recent political meeting, announced that, if he were successful in winning the election, a railway would be constructed from Cobalt to South Lorrain. This would have an important bearing on the future of that section, and would, in all probability, result in the milling ore being hauled to Cobalt for treatment. In a comparatively short time there will be a large excess of milling facilities in Cobalt, and with a reasonable freight rate, the ore can probably be hauled to Cobalt to advantage and treated in some of the Cobalt mills.

**Porcupine** — Shareholders of the Dome Mines had an attack of "heart failure" this week when the shares declined about \$10.00 a share. So far as the physical condition of the property is concerned, there appears to be no justification for such a movement, and although the stock made a comparatively quick recovery, a good many margin holders were shaken out. With labor troubles apparently settled and with sufficient power, the company appears to be in a position to make the largest output in its history. During the recent power shortage the ore broken in the mine was largely increased, and at the first of May was approximately 500,000 tons. The grade of the ore is being maintained around \$12.00 a ton and it is understood that since the first of the month the production is about \$15,000 a day.

The strike vote taken in Porcupine last week resulted in a comparatively small number of ballots being cast, and as a consequence no action was taken by the men. Although other meetings are being called it is doubtful if any trouble will result. While men are by no means plentiful, the McIntyre reports having a greater number of employees than at any time in its history.

Preliminary operations are being started on a number of properties in Porcupine. Preparations are being made to unwater the Ankerite, which has been closed since it was under option to the Coniagas. Surface work is being started on the Martin claim in the same vicinity, and the Rypan Gold Mines in Doloro Township are also doing some surface work. The Beaumont, which was formerly known as the North Davidson, is being unwatered and surface work is being commenced. The South Porcupine Gold Mines Syndicate, with properties near South Porcupine, is calling for tenders for several thousand feet of diamond-drilling.

**Des Quinze** — It is reported that the Des Quinze Power Company, which has been formed to develop the recently acquired power rights on the Quinze River, will shortly make a \$4,500,000 bond issue. The proceeds will be used to retire \$1,200,000 of outstanding bonds of the Northern Canada Power Company, which is one

of the companies guaranteeing the new bond issue. The balance will be used for the construction of the transmission line and the power development.

**Kirkland** — Production of the Teck-Hughes is at the rate of approximately \$90,000 a month, and underground developments indicate that this can be maintained.

At the Wright-Hargreaves, development is now proceeding on the 850 and 1,000-foot levels, which are the two new levels being opened up. The mill is treating between 200 and 225 tons a day, and production is at the rate of approximately \$75,000 a month.

Reports from the Montreal-Ontario state that the crosscut is only a short distance from the point where values were encountered in the diamond-drill hole. This property has had a chequered career, and the reports issued shortly after the reorganization do not appear to have been borne out. It is to be hoped that the new development will give better results; but it is felt that it would be much safer to wait before making any definite statement regarding future possibilities.

**Dome's Bill** — It is understood that no opposition is being encountered by the Bill now before the Dominion House of Commons, which provides for an amendment to the Companies' Act permitting mines and other companies with wasting assets to pay dividends out of profits, although the value of the net assets may be less than the par value of the issued capital. This bill is being sponsored by the Dome's Mines in order to permit them to carry out the proposed reorganization whereby the stock will be split up into shares of no par value for each of the present shares, which has a value of \$10.00 par. As soon as the Bill has been passed the Dome will proceed to effect the change, and an official states that in July the dividend rate will be doubled.

## BRITISH COLUMBIA

**C. I. M. & M. Meeting.** — Thos. Graham, general superintendent of the Canadian Collieries (D) Ltd., was elected chairman of the B. C. Division of the Canadian Institute of Mining and Metallurgy at the Annual Meeting held on the 14th inst. in Vancouver. He is succeeding F. W. Guernsey, who asked to be relieved of office and who was tendered a dinner on the occasion of his retirement. H. Mortimer Lamb, the secretary, in submitting his report suggested the establishment of a branch of the Institute at Stewart, Portland Canal district. Amendments to the Professional Engineers' Act of B. C. have been considered, but it was not thought well to touch that Act at present. The standardization of examinations for coal mine managers' certificates throughout the Dominion of Canada was a proposal that the parent body will be asked to act upon. High tribute was paid to the work and personality of the late J. D. MacKenzie, who was in charge of the Geological Survey Division in British Columbia, and officers were elected as follows: President, Thos. Graham; vice president for the Coast District, H. G. Nichols; vice president for the Coast Interior, M. E. Purcell, Rossland; secretary, H. Mortimer Lamb; administrative committee, S. S. Fowler, Col. J. E. Leckie, Dr. G. Hanson, Dr. W. L. Uglow, Henry Lee; general committee, C. P. Browning, C. M. Campbell, H. S. Munro, A. G. Langley, M. Y. Williams, H. P. Wilson, and P. B. Freeland.

**Coal vs. Fuel Oil.** — In addressing a recent meeting of the Vancouver branch of the Canadian Institute of Mining & Metallurgy, Mr. Thos. Graham, general superintendent of the Canadian Collieries (D) Ltd., uttered a warning against too great a use of fuel oil in British Columbia. This fuel comes from the United States, competes directly with the local coal mining industry, and its use creates an unnecessary exodus of local capital. The United States has reached the peak in fuel oil production and is herself an importer of oil. Lack of supplies to meet the demand now being developed would come in due course and then the neglected coal mines would be asked to step into the gap. It was impossible to double or treble coal production at a moment's notice and the consumers might find themselves without vital industrial and domestic requirements.

**Long Life for Premier Mine.** — Dr. George Hanson, of the Canadian Geological Survey, speaking to a joint meeting of the Canadian Institute of Mining & Metallurgy, the Mining Bureau of the Vancouver Board of Trade, and the B. C. Chamber of Mines, at Vancouver stated that the Premier Mine camp is good for production over an indefinite period. Thos. Graham presided and among those present were Dr. Victor Dolmage, recently appointed head of the Geological Survey in B. C., and W. A. Carlyle, formerly Provincial Mineralogist.

**Britannia Mill's Capacity.** — C. P. Browning, manager of the Britannia Mining & Smelting Co., states that 2,000 tons of ore are passing through the new Howe Sound concentrator every day.

**Gold Dredging in Yukon.** — Burrall & Baird Co., already have started gold dredging operations in the Klondyke Valley and two of the dredges of the New Northwest Corporation on Dominion Creek will open the season's work shortly. The Yukon Gold Co. is not commencing its dredging this year until July 1, but already water has been turned into the \$5,000,000 ditch that feeds the company's many hydraulic plants. Winter dumps of pay dirt are being washed.

**Gold Dredging in Yukon.** — The Burrall & Baird Co. mining man of Spokane, Wn., is reported to have taken an option on 69 gold quartz claims situated on the west of Hawk Inlet, Admiralty Island. Charles Williams, owner of the properties, is to have charge of development work.

**Coal Trade Slack.** — Coal production in British Columbia during April shows a marked falling off as compared with March, the decline amounting to 65,246 tons. The weakness of the market is reflected in the output of each of the three chief coal fields of the Province. At present there are no signs of improvement. All Vancouver Island mines are working half time and the crews of most are being reduced. The only exception to this is the East Wellington Coal Co., operated by J. Grant, which is included among the producers for the first time and which mined 1044 tons. The Canadian Collieries (D) Ltd. and the Western Fuel Corporation of Canada are the mines most affected in this field. The Crow's Nest seems to be facing the necessity of slowing down also, as production there has dropped from 79,509 to 56,651 tons.

The effect of the slump in trade has knocked about 6,000 tons off the Canadian Collieries output at Comox, 7,000 ton at Extension and over 1,000 at South Wellington. It has sent down the production of No. 1 Mine, Nanaimo, Western Fuel Corporation, by approximately 9,000 of the Reserve Mine some 10,000 tons; and of the Wakefield several hundred tons. It has curtailed the Chesley Colliery output, Granby Consolidated Mining & Smelting Co., about 2,000 tons and the Nanaimo Wellington Colliery some 4,000 tons while even the King & Foster Colliery, Nanaimo, shows several hundred tons less production for April than for March.

In the Nicola-Princeton District the Fleming Coal Co. appears to have definitely dropped out of the list of producers. The Middlesboro Collieries show a reduction of several hundred tons and the Coalmont Collieries mined about 2,000 tons less in April than in the previous month. The Princeton Coal & Land Co. is the only company in this field that has the distinction of showing an increase, although the improvement is not substantial.

Practically the same story applies to the Crow's Nest. The Coal Creek Collieries show a reduction of 7,391 tons; the Michel of 15,450 tons; and the Corbin Coal & Coke Co. has about the same production. Incidentally it may be said that the output of coke at Michel fell off in April by about 4,939 tons.

The outputs of the various districts for April were as follows:

|                                     | Tons    |
|-------------------------------------|---------|

**Examinations for Certificates.** — Coal mine officials' examinations, as provided under the "Coal Mines Regulation Act" of British Columbia, will be held on the 29th, 30th, and 31st of May, at Merritt, Nanaimo, Cumberland, and Fernie. There will be candidates at each centre for either 1st, 2nd or 3rd Class Certificates or for all three papers, while a number will offer themselves for mine surveyor's papers. The writing will be done under the supervision of the Mine Inspectors of the districts named.

**Princeton Colliery Reported Sold.** — F. W. Glover, who has been superintendent of the collieries of the Princeton Coal & Land Co., Nicola-Princeton District, has been appointed general manager. It is reported that the coal property has been taken over by English interests, that the measures are to be developed more intensively than heretofore, and that production shortly will be materially increased.

**Coal Bunkers for Vancouver Proposed.** — The installation of coal bunkers on the waterfront of the harbor of Vancouver is proposed by a coal mining company of the Province of Alberta, the intention being to make a bid for the mercantile requirements of that growing Pacific Coast port.

A placer gold mining scheme now contemplated in the Central Otago province of New Zealand provides for baring the bottom of the Karavan River, from which much placer gold has already been won.

## FLOURSPAR IN THE UNITED STATES IN 1922

The United States Geological Survey, reports that the domestic fluorspar-mining industry showed considerable improvement during 1922, recovering from the severe slump of 1921. The improvement was due principally to a larger demand for fluorspar of fluxing grade in the steel industry, which took about 86 per cent of the mineral shipped in 1922.

The producers of about 70 per cent of the basic open-hearth steel made reported that they consumed 72,962 short tons of fluorspar in 1922 and had stocks on hand amounting to 45,637 short tons on January 1, 1923. If the steel companies that did not report consumed a like proportion of fluorspar, the figures given indicate a total consumption in all steel plants of about 104,000 tons in 1922 and total stocks of about 65,000 tons on hand January 1, 1923.

The production during 1922 was 139,700 short tons, valued at \$2,505,000, or \$17.93 per ton. In 1921 it was 34,960 tons, valued at \$724,094, or \$20.71 per ton. Of this the steel companies took by far the larger part, 120,800 tons; glass and enamel factories, 8,700 tons (valued at \$36.49 per ton); hydrofluoric acid manufacturers, 4,800 tons; and foundries, 2,900 tons. The years' imports were 33,108 tons of an average value of \$9.04, of which Canada provided 2,877 tons.

## SOURCES OF PROFIT IN OIL SHALE INDUSTRY.

The probable sources of profit in the oil shale industry, according to Martin J. Gavin, refinery engineer of the United States Bureau of Mines, in the Bulletin 210, recently issued, are crude oil or its products, which ultimately are expected to be motor fuels, burning oils, gas and fuel oils, lubricants, paraffin wax, nitrogen compounds derived from oil, shale gas (which may be an indirect source of profit by reducing fuel costs, as also may refinery sludges if burned under stills), and possibly ammonium sulphate, or similar ammonia salts. There may also be important by-products and specialties, but, as yet, it is not safe to calculate on them.

"CANADIAN MINING ENGINEER, holding responsible position in United States, desires opening in Canada. Thoroughly familiar with all details of mine development and successful record in mine operation. Must give present employers reasonable notice. Reply; Box 583, Canadian Mining Journal Gardenvale, Que."

Nickel Oxide and Metal

Refined White Arsenic

"STELLITE" High Speed Tool Metal

Head Office and Works:

DELORO, ONT.

Branch Offices: 26 Albermarle St., London W., Eng.

### PURCHASE OF GOLD ORES

The attention of prospectors and others is drawn to the provision in the Mining Act of Ontario authorizing the Department of Mines to purchase parcels of gold ore taken out by prospectors and others in developing or working mining claims. Arrangements have been made by which such parcels of gold ore, whether large or small, will be accepted by the Temiskaming Testing Laboratories at Cobalt, and paid for according to the schedule provided for the purpose. The Laboratories are operated under the auspices of the Department of Mines.

This offers a first class opportunity for testing the value of ores on a large scale, and also of turning ore of good quality into money for carrying on further development work. By special arrangements, on less than carload lots, freight rates on the T. & N. O. Railway are reduced 50 per cent.

The Laboratories are also equipped for working out the best methods of treatment for gold or silver ores of a refractory or unusual character.

Full information as to treatment charges, schedule of payments, etc., can be obtained from the undersigned, or from A. A. Cole, Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

THOS. W. GIBSON,  
Deputy Minister of Mines.

Toronto, 12th March, 1923

# Air Compressors

#### Equipment No. 1189

1 Canadian Ingersoll-Rand Air Compressor. Their Serial No. 4597, Type D2 Direct Driven, Cylinders L. P. 25 x 24 Stroke, H.P. 16 x 24 Stroke, Capacity 1625 Cubic Ft. 120 Revolutions, complete with Allis-Chalmers Motor 300-H.P. 120, Revolutions, 25 Cycle, 550 Volt.

#### Equipment No. 324

1 Canadian Ingersoll-Rand Steam Driven Air Compressor. Their Serial No. 5495, Type RS2 Stage, Cylinders 16 x 9 x 16, Capacity 350 Cubic Ft. Also suitable for Belt Drive with 54 x 12 Vertical Air Receiver.

#### Equipment No. 1168

1 Canadian Ingersoll-Rand Compressor, 16 in. Steam 10 in. H.P. Air, 16 in. L. P. Air x 18 in. Stroke, Class C2, Steam Driven, Serial No. 4980, Capacity 585 Cubic Ft.

#### Equipment No. 895

1 Canadian Ingersoll-Rand 1st Half of 16 x 24 in., Class D1, Belt Driven Compressor, Capacity 610 Cubic Ft.

Address inquires to H. W. FURSE

### MAKE YOUR Idle Water Power Pay Dividends

#### IMPROVED KINCAID WATER WHEELS DEVELOP ECONOMICAL and EFFICIENT POWER FOR MINES

The "KINCAID" water-wheels deliver the full theoretical power calculated from a given quantity of water from a stated head.

Using the best materials combined with careful workmanship results in the "KINCAID" being a water-wheel as near mechanical perfection as it is possible to make it. Let us demonstrate its possibilities to you.

## INDEX TO MINE AND MILL SUPPLIES

Addresses of advertisers whose names appear in the following classified index, may be found upon reference to their advertisements. An alphabetical index to advertisers will be found on the page facing the inside back cover. The following regulations apply to all advertisers:—One-eighth page, every issue, three headings; one-quarter page, every issue, six headings; one half page, every issue, six headings; one half page, every issue, twelve headings; full page, every issue, twenty-four headings. Buyers who are unable to find in the in the classification here given such machinery supplies as they desire are invited to write Service Dept., Canadian Mining Journal, Gardenvale, Que., who can in all probability, refer them to proper sources.

## Hardinge Mills in Korea

Where it is difficult to secure repair parts; where only the crudest kind of unskilled labor is available, you will find the Hardinge Mill.

Compare results tabulated here with those in the most favorable localities in this country and see for yourself why the Conical mill is selected for so many similar problems the world over:

|                                       |                                                                                                    |

# The Choice of Men Who Know

THE small user of oxygen and dissolved acetylene can take full advantage of Dominion Oxygen Service.

There are many shops where a comparatively small amount of welding and cutting is done. These shops require the same pure oxygen and acetylene in conveniently handled cylinders and the same assurance of being able to receive their supplies promptly as the mills and factories where larger quantities are used.

We give the small order for one or more cylinders the most careful and prompt attention. Cylinders are of uniform size so that shipping becomes simply a matter of "how many?"

With a widely distributed system of plants and warehouses we are in a splendid position to give you a fresh supply when you need it. This enables you to take care of your requirements satisfactorily and economically.

Our prices show a distinct saving. Be convinced by placing your next order with us.

# Ontario's

# Minerals

PROVINCE OF ONTARIO

DEPARTMENT OF MINES

Hon. H. MILLS, Minister of Mines

## Mineral Areas.

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favorable for the occurrence of minerals, 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver mines of Cobalt occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

## Economic Minerals.

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario:—actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluor-spar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, Portland cement, brick and tile, meet every demand.

## Mineral Production.

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1921 to be worth \$48,128,387, of which the metallic production was \$27,574,202.

The following figures show the rapid growth of Ontario's mineral industry by five-year periods since 1891:

| Year.        | Value.      | Year.        | Value.       |
|--------------|-------------|--------------|--------------|
| 1891 .. .. . | \$4,705,672 | 1906 .. .. . | \$22,388,383 |
| 1896 .. .. . | 5,235,003   | 1911 .. .. . | 41,976,797   |
| 1901 .. .. . | 11,831,086  | 1916 .. .. . | 65,303,822   |

## Dividends.

Dividends and bonuses paid to the end of 1921 amounted to \$23,140,734 for gold mining companies, and \$84,388,185 for silver mining companies or a total of \$107,528,919.

## Mining Regulations.

A miner's license costs \$5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of \$2.50 or \$3.00 per acre, depending on location in unsurveyed or surveyed territory.

## Assay Office.

The Provincial Assay Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

## Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

**The Value of Peat Fuel for the Generation of Steam**, by J. Blizard, B. Sc.

**Analyses of Canadian Fuels**. Parts I to V, by E. Stanfield M. Sc., and J. H. H. Nicolls, M. Sc.

**Graphite** by H. S. Spence.

**Gas Producer Trials with Alberta Coals**, by J. Blizard and E. S. Malloch.

**Summary Report of the Mines Branch, 1920.**

The Mines Branch maintains the following laboratories in which investigations are made with a view to assisting in the development of the general mining industry of Canada:—

**Fuel Testing Laboratory.**—Testing value of Canadian fuels for steam raising and production of power gas; analyses, and other chemical and physical examinations of solid, liquid and gaseous fuels are also made.

**Ore-Dressing Laboratory.**—Testing of Canadian ores and minerals, to ascertain most economical methods of treatment.

**Chemical Laboratory.**—Analysing and assaying of all mineral substances and their manufactured products. Copies of schedules of fees, which are slightly in excess of those charged by private practitioners, may be had on application.

**Ceramic Laboratory.**—Equipment is such that complete physical tests on clays and shales of the Dominion can be made, to determine their value from an economic standpoint.

**Structural Materials Laboratory.**—Experimental work on sands, cements and limes is also undertaken.

**Applications for reports and particulars** relative to having investigations made in the several laboratories should be addressed to **The Director, Mines Branch, Department of Mines, Ottawa.**

**Summary Report.** The annual Summary Report of the Geological Survey is now printed in parts. Applicants should, therefore, state what particular geological report is required, or what subject they are interested in.

**Memoir 108.** The Mackenzie River Basin, by Charles Camsell and Wyatt Malcolm.

# Serving Canada's Mining Industry

It is many years since The Imperial Bank of Canada, recognizing the importance of the Canadian mining industry and realizing the need of banking facilities for those engaged in its development, first opened a branch in Northern Ontario.

Since then the Imperial Bank's service has gradually extended until the mining interests in the rich area between North Bay and Hearst are now linked up by a complete chain of 12 branches.

This Bank's service to the mining industry is not confined to Northern Ontario alone. In all the mining areas throughout Canada the "Imperial" is rendering a valuable and complete financial service.

## :-: EDITORIAL :-:

### IS MAIN ISSUE BEING SIDE-TRACKED?

The interim report of the Dominion Fuel Board, dated April 25th and issued last week, is an excellent document. It is confessedly and obviously, and of necessity, incomplete; but it summarizes in a most admirably concise and clear way the fuel problem as it exists in the various parts of Canada, discussion of which has appeared in a more extended form in these pages during recent months.

Certain conclusions are possible at present, and the Fuel Board presents them, clearly and unequivocally. The danger of depending upon a single source of supply, in a foreign country, to such large extent as at present, is obvious, and we must use Nova Scotia coal, Alberta coal, Welsh anthracite, peat and wood to the fullest advantage, as well as replacing the use of coal by hydro-electric energy to the utmost. All these points are well brought out in the report; but it commits what we consider to be a very serious error of judgment. This error will, no doubt, be corrected in the subsequent and final reports, unless the interests whom we suspect to be hard at work in an endeavour to sway the judgment and influence the decision of the Fuel Board should succeed in their attempt.

The second of the well chosen and cleverly executed charts accompanying the report shows the coal reserves of Canada. All but a tiny fraction are in Alberta. This constitutes the heart of our problem, and try as we may, we cannot make the transportation of this coal to the east any other than the principal problem to be solved. The manufacture of peat fuel, the provision of coke for domestic use, economies in the household use of fuel, all are important; but all sink into insignificance beside the filling of Ontario's coal bins from the mines of Alberta.

It is the failure to emphasize this vital problem sufficiently that we criticise in this interim report. It does not direct the attention of the public to the single point on which most attention should be focussed. It preserves a fine impartiality of judgment among the various phases of the question, while the thing that is needed most just now is that every ounce of energy available should be put into the main issue.

There are numerous well-entrenched interests that will leave no stone unturned to keep the fuel supply of central Canada in its present channels. This is perfectly natural, and insofar as it is an honest attempt to protect personal interests, it is legitimate. It

is not in the national interest, however, that any such personal interests should be allowed to interfere unduly with our decision, and the public should be warned of the danger involved in losing sight of the main issue, in favour of issues of much less importance.

The hauling of Alberta coal to Ontario will, in all likelihood, remain the crux of Canada's fuel problem so long as Canada is a political entity and coal remains the principal source of heat for domestic and industrial use. We have not yet tackled seriously this transportation question. Sir Henry Thornton's offer of \$9.00 a ton, without the requisite facilities for cheap handling or hauling of the coal, is the merest temporary expedient — nothing more than a stop-gap. Mr. M. J. Butler has made a more business-like proposal.

The main issue in the fuel problem must not be side-tracked.

### MAPS OF QUEBEC GOLD AREA READY

The two new map-sheets of the Rouyn gold district of northwestern Quebec have been received by the Geological Survey from the printer, and the accompanying reports by H. C. Cooke and W. F. James, which have been in the printer's hands for some weeks, should also be ready for distribution shortly. Map No. 1987, Duparquet Area, covers the area from the inter-provincial boundary eastward to Lake Dufault, a distance of twenty-four miles, and from Duparquet Lake to the middle of Dasserat Lake, a distance of seventeen miles from north to south. Map No. 1985, of Opasatika Area of like width, extends southward to the southern end of Opasatika Lake.

The geological features shown on these two maps will require careful study, with close attention to the respective legends, which are not identical. On the Opasatika map the conglomerate of the Temiskaming Series and syenite porphyry appear as practically the same blue colour, but are readily distinguished by the identifying numbers.

An outstanding feature is the care devoted to glacial geology, which is an item of the utmost importance to the prospector. Two varieties of stipple, both of them so light as not to obscure or confuse the other parts of the geology and topography, are used to indicate boulder clay, and bedded clay and sand, respectively. Thus for the first time the prospector has the benefit of a map that gives clearly this important geological

feature. For some time the Geological Survey has experimented with these stipples, and now has solved the problem satisfactorily.

These maps have been turned out with a promptitude that sets a record for the Geological Survey, and the geologists, draftsmen and printers who coöperated to speed up the ordinary process of publication are to be congratulated on the result.

### EMPIRE STATESMEN IN CONFERENCE

The Imperial Conference has been called for the 1st October next in London, and the Imperial Economic Conference will meet there at the same time. The need for personal touch and consultation between the heads of the various self-governing Dominions and the representatives of India has recently been growing more urgent. Questions have emerged during the past few months which, perhaps, can only be satisfactorily settled at a Conference of the Empire's statesmen. For example, the signature of the recent treaty with the United States by Canada's own representative alone and not in association with a representative of Great Britain has been regarded, whether rightly or otherwise, as opening up constitutional issues of some magnitude, as to which different interpretations obtain in different parts of the Empire. The forthcoming Conference should do something to clear the air on this as on some other matters.

There are other constitutional problems looming up on the horizon, and it is possible that, in their case also, the forthcoming Conference may make a substantial contribution to their solution. But we confess that, for our part, we regard the questions that must come before the Economic Conference as being second in importance to none. As a result of the war, Great Britain is confronted by an industrial, commercial and financial situation of a far from reassuring kind. In order to obtain the wherewithal to discharge her debt obligations to the United States and also to keep her present population so employed as to support them on a reasonable standard of living, it is imperative for her — to a degree that it has never been before — to find an outlet for her manufactured products. Where is she to find this outlet? That is a question that must come before the forthcoming Economic Conference in a vitally urgent form. For with it is interwoven the question of Great Britain's commercial future and even of her political future as the source and centre of the Empire. For the latter is, and must necessarily be, dependent on the former and on her ability to support her population.

It must be remembered that, of Great Britain's export trade just prior to the war, something like two fifths went to European countries, and of this Germany absorbed about a quarter. Revival of her trade with Germany is unattainable until the reparations question is settled. Indeed, revival of her European

trade at large, on any scale commensurate with her necessities, is almost out of the question until foreign budgets are balanced and foreign currencies stabilized. It is obvious that, as things are at present, Russia must be disregarded from the standpoint of British trade, while, in any case, Germany is more advantageously situated than Great Britain for profiting by any trade openings that may offer in that country. Outside Europe, Japan is both increasing her exports to China at the expense of Great Britain and also taking a leading part in the development of Chinese natural resources. On this continent, the United States tariff must serve increasingly to exclude from the markets of that country even such manufactured products as Great Britain can still produce in competition with American industry. As far as Central and South America are concerned, the United States is now largely in possession of that market as a result of the war which shut off British exports therefrom.

This being so, Great Britain must look for her markets within the Empire. Most of her raw materials and foodstuffs can be supplied within that Empire's wide bounds, and, in view of her war debt to the United States and that country's tariff barrier against exports from other lands, it is to her undoubted interest to draw her supplies from the British Dominions. In India and in Africa, in particular, there are great potentialities for British trade. And, as regards the other British Dominions, while, it is true, each, possessed, as it is, of complete tariff autonomy, is naturally striving to develop its own manufacturing industries, yet each also is under the necessity of importing products from outside its borders. In such circumstances, it should not be beyond the competency of Empire statesmanship to devise some well-considered plan whereby inter-Imperial trade may be fostered and developed. So far as Canada is concerned, apart from any high Imperial grounds, there is every reason why we should restrict our purchases from other countries and buy instead from Great Britain — a customer that buys so much from us in the present and is sure to buy increasingly from us in the future.

It is because the subject of closer Empire trade is bound to be canvassed at the forthcoming Economic Conference with unprecedented concentration that we attach such importance to the meeting of that body next October. The objective at which we should aim is for every Empire citizen to purchase Empire-made goods. The manner of attaining that objective need not be discussed here and now. But the urgency of Great Britain's economic situation will doubtless be made fully apparent at the deliberations next October.

---

Australia is ruled by a Labour government, and is enjoying the unsettled conditions naturally consequent upon such rule. The extremist Opposition is

socialistically inclined, or "red". A contemporary writer in Melbourne remarks that this "is the difference between tweedle-dum and tweedle-dee, for everyone knows that what extremists desire is power like that of Lenin and Trotsky, while the other party are only envious of the possessions of others. Our sister dominion is learning by hard experience the result of putting political control in the hands of leaders whose guiding ideas consist of untried theories instead of the well-tried principles that naturally form the basis of British governmental practice. The present troubles of Australia may well constitute a warning to us Canadians, lest we similarly lose sight of so valuable a part of the British tradition.

### SPIRITS OF STAG BAY

On rock-ribbed shores the ocean roars,  
The wind blows cold and dreary;  
Beneath a tent, a wanderer spent,  
Worn out, and over-weary,  
Reclines his length, devoid of strength,  
And low emits this query:—  
"Why came I to this country bleak and froze?  
"Why came I here to barren Labrador?  
"Why hearkened I to mister Bellew's bull?  
"And why did I my freight so quickly pull"  
"By mosquitoes I've been stung  
"And my withers they are wrung;  
"But the sting I got in good old Montreal  
"Was the sting that really hurt,  
"Was the touch that did me dirt,  
"Yes, the sting that I was stung in Montreal."

#### Spirit of Labrador:—

"Who seeks his fortune in my hostile waste  
"Must of disaster and distresses taste."

#### Spirit of Bellew (by radio):—

"I still have forty acres to be sold.  
"These acres promise bucketsful of gold.  
"Co-operate a little while with me,  
"And you shall see exactly what you'll see."

#### Spirits of St. John's and Sydney:—

"A murrain on the critic and the crab!  
"A blessing on bold Bellew and his grab!  
"For our boats they all are chartered,  
"And our merchandise is bartered,  
"And the gold pours in like blazes ere it reaches  
Labrador,—  
"Ere it reaches Labrador, where the winds are keen  
and froze—  
"We have prospered more this season than we ever  
did before."

#### Spirits of Co-Operative Investors:—

"We saw it in the papers, boldly printed;  
"Neither figures, facts, nor glowing hopes were  
stinted.

"Though a few pale protests rose,  
"Bellew led us by the nose:  
"And our money we have lost it,  
"Just as much as if we'd tossed it  
"In the waves that lave the shore,  
"Rock-bound shore, of Labrador."

#### Spirit of the Canadian Mining Journal:—

"Weep no more these briny tears and salt:  
"We told you so, it's all your own darned fault!"

#### Spirit of the Geological Survey:—

"This woe, these lamentations, are misspent;  
"We warned you wisely,—after the event."

#### Spirit of Administrative Justice:—

"Too bad these culprits have got clean away:  
"Should this recur, then they will rue the day!"

#### Spirits of Daily Newspapers:—

"They paid us for advertisements, you know;  
"We took the cash and let the credit go."

\* \* \*

On rock-ribbed shores the ocean roars—  
It is the old, old, story.  
Oppressed by flies, the wanderer dies;  
His soul goes on to glory.  
But, ere he dies, "Eheu!" he cries,  
"To think of my forgetting  
"That no place more than Labrador  
"Demands mosquito-netting!"

J. C. M.

### THE KENO HILL MINES

The results of the winter's campaign of ore transportation from the silver-lead mines of Keno Hill, Yukon Territory, are recorded in a recent issue of the *Dawson Weekly News*. The allied companies, Keno Hill, Ltd., and Yukon Gold, have hauled out 5,000 tons of ore to the Stewart River at Mayo, while the Treadwell Yukon Company has brought out 4,000 tons with its caterpillar tractors. Smaller shippers are the Shamrock claim, 100 tons; the Gamble claim, 50 tons; and the Gold Queen claim, 13 tons, all of high-grade ore.

There is now a producing mine on the McQuesten or western slope of Keno Hill. On the Sadie claim of the Yukon Gold Company a new shaft has opened up a promising shoot of very rich ore, mostly composed of grey copper. The vein is said to be a continuation of the Treadwell Yukon vein.

The developed ore of the Keno Hill, Ltd., vein has been stoped out during the winter, and a crew of miners are now at work developing a supply for shipment during the coming winter. Development of the Treadwell Yukon has been in progress during the winter, and ore of remarkably high grade is reported to have been opened up, particularly on the 300-foot level, where ruby silver is abundant.

It is estimated that 20,000 tons of ore will be shipped from the Keno Hill mines next winter, and that, due to improved transportation facilities, it will be profitable to ship ore of a lower grade than at present.

# LETTERS FROM SOUTH LORRAIN

## II PERSONAL AND GENERAL

NOTE — In the first of these letters, June 1st issue C.M.J. the third last paragraph should read: — "I doubt if more than two or three mining men in the North and otherwheres believed until quite recently that Dr. Bell's judgment would be vindicated. South Lorrain in general, and the Keeley mine in particular, were regarded not as merely moribund, but as dead, etc."

Times have changed profoundly since the early days of Cobalt, and changed for the better. The restrictive geological thought of those days has largely disappeared. It may be for the ultimate good of all concerned that South Lorrain's development was postponed until now. That the district will be opened up rapidly is certain. The two (and there are only two) producing companies have large acreages under option or under purchase agreement. The Huronian Belt Company, which holds a preponderating interest in the Keeley, is opening up the Maidens property, lying to the east near the shores of Lake Temiskaming. The claims have definite promise. The Mining Corporation has a large group of contiguous claims forming a solid block surrounding the Frontier mine. Both companies are planning comprehensive campaigns of sinking, underground exploration, and diamond-drilling. Other companies, syndicates, and individuals, are bringing in equipment for systematic work.

The other side of the shield is represented by one widely advertised property, on which no work was being done at the time of my visit, and which has absolutely nothing to recommend it save the indeterminate possibilities of location. I refer to the Lorrain Consolidated. This concern runs a very fair chance of giving a black eye to the district generally. The promoters seem to be doing their best to trade on the established reputations of the producers, and in doing so to discount the future of their own property to a dangerous degree. This is mischievous and superfluous.

In the main, however, the spirit animating South Lorrain is sound. The camp is reaping the full benefits of cumulative experience, hard won in Cobalt, and of extraordinarily improved mechanical equipment.

When it is borne in mind that the Frontier has shipped this year high-grade ore containing about 750,000 ounces of silver; that the Keeley is producing about 140,000 ounces of silver per month, will soon largely increase (possibly double) this amount, and is adding more to its reserves than is being taken out of the mine; that more than a score of new possible producers will be opened up this summer,—it is hard indeed to understand the lassitude of the Provincial Government in the matter of road-building. The road from North Cobalt to Silver Centre, 118 miles, was bad enough when the writer drove in to the latter place; but it was incomparably worse on the way out. Two wet days had converted it into an almost continuous quagmire. Desultory attempts to mend matters were being made by Government road-gangs, — with the usual result. With Cobalt, North Cobalt, and much-afflicted Haileybury depending for their continued existence on the growth of mining in South Lorrain, it seems wonderfully short-

sighted on the part of the Government not to act with vigor and despatch.

However, abusing governments is too common an indoor sport to be particularly interesting. My earnest wish is that the Premier and his entire cabinet should be driven over this *via dolorosa* in a seatless express wagon, on a rainy day.

\* \* \*

That best of all breeds, — now, now, let us moderate our transports! — that peer of any breed, the Bluenose, is well represented in South Lorrain. Even that pseudo-Bluenose, the Cape Bretoner, answer the roll-call. The Nova Scotian plays a part in mining communities comparable to the part played by vitamins in modern dietaries. Therefore he may appositely be called the "vitaminer," Modesty forbids us to pursue the subject farther.

\* \* \*

With incomplete and partly improvised equipment, most creditable results have been obtained at the Keeley mill. The mill superintendent, Mr. M. R. O'Shaughnessy, (a Bluenose), has had long and varied experience in handling recalcitrant mills and obstinate ores. The task of concentrating oxidised silver ores of very variable metallic tenor, along with unoxidised ores is neither simple or easy. To achieve a recovery averaging about 90% on this class of milling ore is something to be proud of.

\* \* \*

From experience up to the present a few generalizations can be drawn as to the character of the known veins and vein systems. The Woods vein, which is the central — though not necessarily the most important — feature of the vein systems of the Frontier and the Keeley, has a general north and south strike. In a paper read before the Institution of Mining and Metallurgy, London, Dr. Bell states that this vein occupies a fault resembling that at Cobalt Lake, but that the Woods vein is stronger and shows much less "gouge". It is not anywhere exposed on the surface, but can be traced for the reason that it follows a narrow, low, swampy depression known locally as Woods Valley. The vein occupies a fractured zone, ten feet wide. Sometimes there are three, four, and even five feet of solid ore. Again the vein will be split into two or more stringers over a width of four or five feet. In these cases the fractured rock is usually impregnated with leaf and wire silver, or with fine argentite or ruby silver. But the Woods vein is exceptionally wide. The other known veins (and they are numerous) are usually not more than two to three feet wide, and often much less. The suite of metallic vein minerals is not markedly dissimilar to the vein minerals of Cobalt. The gangue in the unoxidised portions of the veins is also similar to that of Cobalt veins. It is made up most commonly of calcite, dolomite, and quartz. A pink, silicified carbonate is not uncommon. What is taken to be a healthy indication of high-grade ore is a dense, very dark, finely banded quartz and calcite, containing smaltite and, generally, fine native silver enclosed in the smaltite. The vein material in the oxidised zone is a highly decomposed, soft rusty material containing

# Natural Gas and Petroleum Resources of Western Canada

## 1—GENERAL CONDITIONS AND EXPLORATION

BY NEWTON W. EMMONS.

For the past few years, in fact ever since the close of the Great War, when we have been able to turn our attention to other things besides the saving of civilization, the petroleum industry, particularly that branch of it which deals with the discovery and development of new areas of supply has been much in the limelight, and our daily press has had a good deal to say on the subject, much of which is inaccurate to say the least.

Great stress has been laid upon the statement, emanating from varying sources, that the known resources of petroleum are being rapidly exhausted and that the end of the supply is in sight, even though such an event be placed several decades away; and it has been suggested that the time is not far distant when the motorist will have to depend upon some other fluid than gasoline to drive his car. There is no question that the production of oil in some fields is declining, that their present production is much smaller than a few years ago, and that their complete exhaustion is only a matter of a comparatively short time, notably the light-oil fields of Mexico (which have declined some 80% in the past two years), and some of the oil-fields in the Eastern United States. But these declines have been much more than offset by the greatly increased production from the newer fields in the States of Oklahoma, Wyoming, Montana, Texas and California. In this last State four new fields have been discovered during the past year, which have not only added tremendously to the immediate oil production but, from the great thickness of the sands, promise a long life. Added to this is the fact that in California deep drilling is now practised and wells are being successfully bored to depths of over 6,000 feet. (The Standard Oil Co., of California has just completed a well 6,680 feet deep,

which establishes a new record of depth for a rotary-drilled well). This adds over one thousand feet vertically of possible new productive ground to what has been previously developed, as it is now commercially profitable to penetrate to the deep sands. It is interesting to note, in this connection, that in California during the past year there was added to the oil storage capacity, tankage to the extent of 7,000,000 barrels, because there was no immediate market for the greatly increased production; and also that, according to the figures of the American Petroleum Institute, there was oil in storage on December 31st, 1922, to the extent of 61,184,928 barrels, (about 214,150,000 imperial gallons) with a daily production in December last of 565,000 barrels, to which could be added another 100,000 barrels at any time from wells belonging to the larger operators that were shut in, being held in reserve.

### U. S. Production and Reserves Increasing

In the first five months of the present year the California production of crude oil has been increased to about 700,000 barrels daily, at which figure it will probably be held for the very good reason that no facilities exist, nor can they be readily obtained, to take care of a greater output.

In addition to this increase of production in California, increases are also recorded in all the other producing fields of the United States with the exception of those of Indiana, Kentucky, Colorado, Tennessee and the coastal district of Texas, in which places there has been a falling off. The total crude oil in storage in the United States at the end of March last was, according to the figures of the United States Geological Survey, 258,026,000 barrels, since which time it has increased materially because the production is greatly in excess of the demand. To stimulate the demand, prices of crude oil have been reduced several times of late and there is every indication of their going lower. On May 14th the following prices per barrel of 42 U. S. gallons were quoted:—

|                 |                  |
|-----------------|------------------|
| California      | \$0.60 to \$1.04 |
| Wyoming         | 1.25 to 1.70     |
| Gulf Coast      | 1.30 to 1.75     |
| Mid-Continental | 1.10 to 2.20     |
| Central States  | 1.35 to 2.18     |
| Eastern Fields  | 1.00 to 3.25     |
| Sunburst, Mont. | 0.80             |
| Petrolia        | 2.58             |

The governing factors in arriving at the value of any given crude oil are the percentages of gasoline, naphtha, kerosene and lubricating oil contained in the crude and the cost of getting it to the refineries and market.

### Importance of Oil Production in Canada

It may be contended that the foregoing brief summary of the oil situation is of no particular interest to Canadians and has no bearing on the search for oil nor on the profits to be obtained from its discovery and exploitation. Such a contention is erroneous, for the reason that any oil discovered in Canada will have to com-

annabergite and erythrite near the surface. At greater depths these minerals become increasingly rare.

At the diabase-Keewatin contact there is little, if any, enrichment. The most persistent and spectacular shoots occur at varying distances from the contact, but relatively close to it. It is noteworthy that, with the exception of the Woods vein, the veins are found to carry ore more profitably when the dip is steep than when the dip flattens.

On neither the Frontier nor the Keeley has the intricate network of veins been more than incidentally explored. Underground prospecting demands experience, patience, ceaseless watchfulness, and, above all, courage and initiative. A considerable amount of "blind" work must be done because of the ever-present fear of missing something worth while. A visit underground at South Lorrain is at first eminently confusing. However, as one gets his bearings, it becomes intensely interesting to read the visible records of success and disappointment. Evidences of the latter are more numerous than evidences of the former, but success when it does come makes up an hundred-fold for all blanks drawn.

J. C. MURRAY

\* Petroleum Engineer, Vancouver, B. C.

pete in the open market with that of like grade produced on the other side of the line, particularly in view of the fact that the refineries are in the hands of the large oil companies and the prices are established by them, based on the demand for their refined products and the amount of suitable crude oil offered. The independent refiners, of whom there are a few, either own wells or pay the same prices as the big refiners.

The importance of the discovery of producing oil fields in Canada rests not so much upon a present lack of supply as it does upon having the source of supply within the Empire, because, in the event of war and the supply of crude oil, which Great Britain at present obtains from foreign countries, being cut off, she would then have resources of her own upon which to fall back. In time of war, as well as in time of peace, not only is crude oil of vital importance to the life of the nation and its commerce, but gasoline is even more so, as without this latter the operation of air-craft and motor transport would be most seriously handicapped. Many chemists are engaged in research work, the object of which is to obtain a greater yield of gasoline from crude oil, and many improvements have been made in the art of petroleum distillation within the past few years, that have accomplished much in this direction, particularly the "cracking" process by which the heavier hydrocarbons are broken up and re-grouped into lighter compounds by a molecular rearrangement.

### A Vast Field For Exploration

The attention of the geologist and petroleum engineer, in their search for petroleum-producing territory in Canada, has been directed to the great central plateau region lying to the east of the Rocky Mountains and extending from the United States boundary to the Arctic Ocean, because here are found not only similar strata, of the same geological age as those proven to be productive in the United States, but because of the existence of enormous deposits of bituminous sands that are clearly the residue of an extensive oil field from which the lighter hydrocarbons have evaporated. Unfortunately much of this territory, particularly north of latitude 56°, is extremely difficult of access, owing to lack of railways, or even roads, and the expense of thorough exploration and drilling is prohibitive to any but the financially powerful organizations that are now engaged in the work and to whose enterprise and perseverance great credit is due.

In spite of these handicaps, however, much work has been and is being done north of latitude 56°, with as yet inconclusive results. The existence of oil has been proved, even if the extent of the field and its productivity have not, and there is good reason to believe that commercial oil-fields will be developed in this part of the country even though it may take additional years of persistent effort and the expenditure of large sums of money.

### The Prospective Coutts Oil-Field

In the southern part of this territory, more particularly in southeastern Alberta, renewed interest is being taken because of the discovery in 1922 of an oil field twelve miles south of the International boundary in Toole County, Montana, known as the Kevin-Sunburst field, in which there are two proved oil-producing formations, one in the Kootenai (Dakota-Kootenay of Alberta) of Lower Cretaceous age, and the other in the Ellis of Upper Jurassic age. The structure in the Kevin-Sunburst field is that of a broad dome, superim-

posed on a northward plunging anticline that extends from south of Great Falls, Montana, for one hundred miles into Alberta, and the oil-field as at present outlined by drilling lies round the higher part of this dome, its northern limit being about ten miles south of the border. The wells are not deep, being from 1500 to 1,700 feet, and are not in the "gusher" class, recently completed wells giving from 30 to 50 barrels a day.

There is no reason to believe, however, that the accumulation of oil into commercial pools is confined to this Kevin-Sunburst dome or that similar structures do not occur along the same anticline in the Province of Alberta; but it is probable that the oil horizons are here at a considerably greater depth owing to the northward dip of the arch.

In 1918 the Grand Trunk Pacific Development Co. drilled a test well in Sec 1. Tp. 1., R. 12 W., 4th Meridian of Alberta, a short distance north of the Montana line, but got only a "show". This well was drilled to a depth of 2900 feet and passed completely through the Dakota-Kootenay and Jurassic formations that are productive in the Kevin-Sunburst field. From our present knowledge of the underlying rock structure in northern Montana and southern Alberta it is evident that this Grand Trunk well was located too far to the east. Several other tests were drilled in the Sweet Grass Hills country (southern Alberta) with negative results, but all were too far east to catch the northward continuation of the Sweetgrass arch (the name given to the anticline upon which the Kevin-Sunburst dome is superimposed), the axis of which, from the latest available data, will cross into the Province of Alberta to the west of the town of Coutts. Here several tests wells are now being drilled, the results of which are awaited with interest.

### The Productive Field at Okotox

In southwestern Alberta is situated the only field so far developed in Western Canada that has commercial oil production. This is the Okotox field, 35 miles south and a little west of Calgary, from which a high gravity oil is being produced. This field is described in detail in Memoir No. 122 of the Canadian Geological Survey, to which the reader is referred for complete information. It is interesting to note, however, that the oil and gas in this Okotox field comes from the same geological horizon as that which contains the upper producing sands of the Kevin-Sunburst field, namely the Dakota-Kootenay beds of the Lower Cretaceous.

In other parts of Alberta much drilling has been done in an endeavour to find oil in commercial quantities, but up to the present the results are not encouraging. Oil has been found in a number of these wells, it is true, but in no instance has it been in sufficient quantities to make its recovery profitable under present conditions of transportation, market, and high cost of operation. But the possible, I may safely say probable, oil-producing area is of such great extent and so much of it is remote from transportation that it will be many years yet before it can be definitely stated that there are, or are not, commercial oil-fields in western Canada.

### Great and Unrealized Importance of Gas Field

It must not be thought that all this searching and drilling for oil has been without important results, or that the money thus expended has been useless, because such is not the case. As a matter of fact the existence of some of the largest natural gas fields on the North American continent have been proved by this work, individual wells having "open flows" of from one to

thirty million cubic feet of gas per day. Some of this gas is "dry" but much of it contains gasoline that can be recovered and sold at handsome profit, and all of it will ultimately become a source of revenue; will be used for domestic and power purposes, or manufactured into products of commerce for which there is an existing market and increasingly active demand. This potential source of gasoline is of the greatest importance to the Dominion, second only to the finding of a great oil field; and, should the output be greater than can be absorbed by the domestic market, there is an export demand of no mean proportions; for example there was imported into the United Kingdom from the United States and Mexico for the week-ending April 9th, over two million gallons and the exports of gasoline from the United States amount to hundreds of millions of gallons per annum.

The subject of this natural gas, the extraction and recovery of its contained gasoline, and the utilization of the residue-gas will be dealt with in a second article.

### PERSONAL AND GENERAL

Dr. Oliver Bowles has been appointed superintendent of a new mining experiment station established by the United States Bureau of Mines at Rutgers College, New Brunswick, New Jersey. Dr. Bowles is a Canadian and graduated from University of Toronto in 1907. His specialty is non-metallic minerals.

Ontario's gold deposits were discussed at the meeting in New York last month of the Society of Economic Geologists, where Dr. W. G. Miller, Mr. C. W. Knight and Mr. P. E. Hopkins addressed the meeting on various phases of mining in Ontario and the geology of the mining districts.

Dr. John A. Allan, of the University of Alberta, is on a business trip to the East. He has already visited Ottawa and Montreal and is on his way further east.

Mr. Hugh McMillan, mine superintendent of the Keeley, on being transferred to the superintendency of operations at the Maidens property, was presented with a gold watch and chain by the Keeley employees.

Prof. S. H. Graham, who is associated with Mr. J. B. Tyrrell, has gone into the Rouyn gold field.

Mr. C. M. Odell, of the Dominion Coal Company, who returned recently after a trip through the Canadian West, has been promoting in Sydney the idea of closer coöperation between East and West.

Dr. J. Mackintosh Bell returned last week from the Rouyn gold district, where he inspected claims held by the Huronian Belt Company of London, of which he is the Canadian representative.

Mr. Clifford E. C. Smith is at the Ankerite property in Porcupine, which has been unwatered preparatory to a campaign of active development by a New York syndicate.

Mr G. P. Mackenzie, Dawson City, gold commissioner for the Yukon, has received instructions from Ottawa to establish a separate mining district round the Mayo silver camp. There is already a sub-recorder's office in Mayo, in charge of Mr. R. L. Gillespie.

Mr. James Harkness, one of the pioneers of South Lorrain and the owner of a number of claims there, has just returned from a business trip to Buffalo.

Mr. L. R. Clapps has been appointed resident manager for Granby Consolidated of the mine at Copper Mountain and the adjoining mill at Allenby, B.C.

Mr. David Brownlie has severed his connection with Messrs. Brownlie and Green, Ltd., of London and Manchester, and is now engaged in private practice at 46 Grange Road, Ealing, London, W. 5. He continues to specialise in the use of coal, particularly in its carbonisation.

Dr. J. Auster Bancroft, of McGill University, has arrived in Anyox to do special geological work for Granby Consolidated during the summer months. He will pay particular attention to the Sultana, Sunshine, George and Outsider Groups.

### MEETING OF SOCIETY OF ECONOMIC GEOLOGISTS

The Society of Economic Geologists held its first, what may be called independent, meeting in New York on May 18 and 19. This Society was organized a couple of years ago, but has heretofore held its meetings along with the Geological Society of America or with the American Institute of Mining and Metallurgical Engineers. The recent meeting was considered to be a great success, about fifty members being in attendance. It is likely that hereafter this Society will hold its annual meeting in May. The following representatives of Canada were present at the meeting, viz., W. G. Miller, C. W. Knight and P. E. Hopkins of the Ontario Department of Mines. There is room for specialized societies such as this in North America as owing to the large population on this continent, most scientific societies have become too large and unwieldy, and there is not a good opportunity for fraternizing and becoming acquainted in such a way as there is at the gatherings of smaller societies.

### NEW GRANBY PROPERTY

*The Granby News*, published at Anyox, B. C., reports that active exploration work will be commenced immediately by the Granby Company, according to the announcement of the General Manager, on the Sultana group of claims. This property is situated at Boulder Creek, ten miles from Seaton, which is about one hundred and twenty-five miles east of Prince Rupert. There were some six or eight claims originally comprised in this group, but this number has since been increased to fourteen. The ore is high grade carrying copper, silver and gold. Sampling across the sixteen foot ore body gave returns of sixteen ounces silver, three and a half per cent. copper, with gold values.

### NEW FELLOWS OF ROYAL SOCIETY OF CANADA

At the meeting of The Royal Society of Canada, held in Ottawa May 22-24, the following geologists were elected Fellows of the Society: A. G. Burrows of the Ontario Department of Mines; E. L. Bruce of Queen's University and H. C. Cooke of the Dominion Geological Survey. The chief item on the "menu" at the meeting of the geological section was a discussion of pre-Cambrian nomenclature and classification.

The geological section of the Royal Society, which is one of the oldest societies in Canada, having been founded in 1879, has been considerably enlarged of late years and shows more life. For many years there was little encouragement to geologists to become members of this Society. The geological section now numbers about thirty fellows.

# Another Coal Producer Ready

SHAFT No. 1B, AT GLACE BAY, NOVA SCOTIA,  
SUNK AT RATE OF 81 FEET PER MONTH

By JOHN MOFFATT

Floating in the breeze from the head frame of No. 1-B Colliery on a beautiful May morning, the Union Jack attracted the attention of the populace of Glace Bay. The glorious old flag was unfurled to tell to the mining world that a new shaft had pierced through to the coal, and another great producer was added to the chain of large collieries, dotting the shore line from Port Morden to Little Bras d'Or. Standing within a quarter of a mile of one another there are now three large shafts, which, when all are producing, will give a daily output ranging from seven to eight thousand tons. The flag was intended to do more, however, than make a mere announcement, for the construction department of the Dominion Coal Company had decided to do three things last November, when it was purposed to sink the shaft. These were, to reach the coal on or before the 15th of May, to do it within a certain estimated cost, and to practise the principle of "safety first" so diligently that the whole force would be on the job when finished. This was all accomplished, and the notable achievement was honored by the flag we love the best. There in the early morning stood the hardy shaftsmen, who had so heartily co-operated to bring this great work to successful completion. Through all the months of a most severe winter, these men had labored in one of the most hazardous of occupations, and had attained their objective. That this should have been accomplished without a fatal or a serious accident (the compensation paid out being almost nil.) gave great satisfaction to all who had to do with the work. That the promise of a bonus had stimulated the miners to greater effort, yet had not led to undue haste or to accident, was indeed cause for congratulation. It showed a perfection of organization that was scarcely to be looked for in such work; for shaft-sinking is a problem in itself, and from the day the first sod is turned until the last shot is fired and the muck loaded away there is constant danger. For protection, hoisting was done through a steel cradle, non-twisting ropes being used on the buckets.

The main points to be considered in shaft sinking are: size of shaft and number of compartments required; organization of working force; sinking plant, engines, etc.; drilling; explosives and blasting; ventilation; unwatering of shaft during sinking; disposal of muck; shaft lining or timbering; speed and cost of sinking.

## Timbering

A description of the timbering of this shaft may be interesting. It is to be a two-compartment shaft, rectangular in shape, 13' 4" by 31' 2" outside the timber, and is timbered and lined according to the square-set method with hard pine throughout. This timber was installed in 36-foot sections, each section consisting of 6 sets of frame timber, about 6 feet apart, and the whole section supported on 8' by 10" bearer beams, spanning the shaft and set about 3 feet into the rock on each side. Each set consists of 2 wall plates 8" by 10", 2 end plates 8" x 10" (pieces parallel to the short

axis of the shaft), and 4'6" posts or studdles to keep the plates in the proper horizontal position. These plates are framed with tenons and the posts dapped into place, so that they go together without the use of bolts or nails.

In order to divide the shaft into the necessary compartments for cages and pipe lines, cross timbers called divides or buntions are put in (in the same places as the plates) and extra posts are placed opposite the end of each buntion. These buntions are framed into the wall plates with a V-shaped tenon, so that the weight of the timber keeps them in place. Each set is framed from templates on the surface and marked so that when it is sent down the shaft it matches and goes into place without any extra cutting or trimming.

The rock sunk through was principally grey shale, which when exposed to the atmosphere slakes and spalls off. To prevent any of this from falling into the shaft, the space behind the timber sets is filled with three-inch hard pine plank placed tight, and the space between this lagging and the rock walls packed with broken rock to keep the wall rock from starting.

## Speed of Sinking

The best month's work was in March, when progress of 105 feet was made, and 1,924 cubic yards was excavated. In addition to this sinking, 136 feet of shaft was timbered. The average rate of sinking was 81 feet per month, which, considering the season of the year, the size of the shaft, and the difficulty the men had in getting to work, is well worth noting.

Comparisons of shaft sinking gives little information when the nature of the ground and other difficult conditions met with are not known. For instance in one month a shaft was sunk to a depth of 427½ feet. This was exceptional, but when the size of the shaft is considered, it being only 5'6" by 15 feet, Dominion No. 1-B far out-stripped it when it comes to the displacement of rock, as 85 feet per month would then equal the above record. In addition the shaft was timbered and lagged as described.

The following is a list of some shafts and speeds of sinking:

Tamarack No. 5 Lake Superior District, 29'2" x 8'10" — 5 compartments. Total depth 4,580 ft. Best rate of progress 85.75 ft. per month.

Pocahontas Colliery Shaft W. Va., 14'x22"—3.33 feet per day.

Pennsylvania Anthracite Shaft, 44' x 24"—952 ft. deep, 90 ft. per month.

Rand Shaft, South Africa, Durban 18'x8' — 1,444 ft. deep, 87 ft. per month.

Summer West, 28'x8' — 3,408 ft. deep, 130 ft. per month.

Jupiter, 28'x8' — 3,752 ft. deep, 135 ft. per month.

Gov. Gold Mining Areas, Rand, 45'x10' — Rate 194.3 ft. per month at depth of 1971'.

An average rate of progress for 10 shafts put down in the Rand district worked out to be approximately 140 ft. of advance per month. A similar record for 11

shafts sunk in the United States during the same period gave a progress of approximately 100 ft. per month. The variation is accounted for by the difference in working conditions, and also by the fact that all the South African shafts are in the same locality and hence have their methods standardized.

The drills used were the Waugh 55 Clippers with 78 inch hollow hexagon steel. The explosive used was 40 per cent. Polar Forceite and it took about 1.4 lbs. per cubic yard of rock in place. Blasting was done by electricity from the power circuit, using delay action fuses, the usual practice of shooting first the sump or wedge being followed.

The shaft was ventilated by an electric driven blower fan on the surface and the air conducted to the working face by flexible canvas tubing.

Very little trouble was experienced from water, most of it draining away through a bore hole that connected with the underground workings of the Phalen seam.

and an I beam 12"x5" is set in the floor between stanchions, making a complete rectangle of steel, concrete being filled in between the webbs of adjacent frames.

The shaft is designed to handle 2,500 tons per shift of eight hours, but provision has been made to install double-decked cages at some future date, if it should be found necessary, which will double the capacity of the shaft. Every endeavor has been made to install labor saving devices and to reduce manual labor to a minimum.

A large central pumping station will be placed at the pit bottom, delivering 2,500 gallons per minute against a 680-foot head. Sulger electric turbine pumps being used.

### Mine Equipment

In order to take a considerable part of the large volume of air necessary to ventilate this mine, a dumb drift is driven from the main airway 100 feet to a seam of coal 100 feet from the shaft bottom, which

The crew that sank No. 1 B shaft at Glace Bay

The rock was hoisted in iron buckets, three feet in diameter by three feet high, to the bank head, where it was dumped into storage pockets and from these into railway cars.

### Equipment of Shaft

The pit bottom is 23 feet 6 inches wide. The cage holds two pit tubs side by side, each carrying 2½ tons of coal. The track gauge is three feet. Electric locomotives will bring 50 cars into the mine bottom siding. From there a creeper regulates the delivery of the tubs to the cage and at a distance of 50 feet from the cage the tubs run by gravity onto it.

A special regulating device delivers the tubs to the required track. When the car stops are lowered the empties run off by gravity to a creeper which distributes them to the empty locomotive siding, from which they are taken to the haulage.

The shaft bottom is very strongly supported, by artificial means, due to the only possible location of the shaft being in an area where pillars of none too great size had previously been left. At the wider part of the pit bottom, steel stanchions of Bethlehem section 12"x12" support the roof girders of 12"x18" section

delivers the air into the shaft.

The main shaft bottom level is equipped with electric traction haulage. This main level is of a most substantial character, well supported throughout in the roof with steel. The track is laid with 60 lb. rails. A wide side has been left for travelling, there being three feet between the wall and the side of the pit tub. The electric cables are hung on the opposite side and guarded by two boards hanging down. Workmen will be taken to work in mine cars along this road.

There is about a mile of rise coal and an unlimited area seawards. The coal above the bottom will be taken in by gravity. Trolley haulage locomotives will only be taken in as far as the first working headways, and, to insure safety, storage battery haulage will do the most of the inside work. Of course there will always be the small donkey engines inside operated by compressed air.

Large double airways, most substantially built, are carried right into the workings, the object of the management being to make everything of a permanent nature in view of this shaft being the last from this point of land, the entire workings being submarine

The plant was sunk by the Construction Department, of which Mr. W. H. Graham is Superintendent, D. Colquhoun and William McEwitt, being general foremen, in direct charge. The construction of the pit bottom, the main level, and all underground work was done under the direction of Walter Herd, Mining Engineer for the British Empire Steel Corporation.

### COKE FOR DOMESTIC USE

Most interesting information regarding the making of a by-product coke in Nova Scotia and the possibility of its manufacture in industrial centres for domestic use was disclosed recently when Mr. Frank E. Lucas, for nearly years connected with the coke plant at Sydney, gave evidence before the Senate Fuel Committee. The output there at present is a little over 1,000 tons of coke a day.

A good many of the employees of the Company in Sydney already use coke breeze (pieces less than three-quarters of an inch in size) in their base-burners instead of anthracite coal. Last winter a few thousand tons of coke were sent to Halifax, and there it found a very ready market through local dealers in competition with anthracite coal, with which it compares favorably, ton for ton, in heating value. One dealer reports that he still has plenty of anthracite on hand because he cannot sell it in competition with coke at \$15.00 a ton.

### Industrial Value of By-Product Plant

The value of a by-product coke plant to an industrial community is strikingly put by Mr. Lucas, thus: "The manufacture of one ton of coke made from Nova Scotia coal produces enough gas for cooking for the average family for a year, enough fertilizer for a large garden, enough tar to spray the road in front of your lot, and enough motor fuel to drive your car fifty miles. I regard the installation of by-product plants in, say, Montreal and Toronto as one of the greatest economic assets the country could have. It would be an asset in the industrial development and building up of those areas practically equal to what happened in either because of the introduction of cheap hydro-electric power."

The size of a by-product plant has, of course, much to do with the cost of its products. A 1,500-ton a day plant, said Mr. Lucas, would turn out coke at about 30 or 40 cents a ton less than a 1,000-ton plant. In a 100 ton plant, such as those now used in some cities to supply gas, the cost would be much greater. A town of 60,000 to 80,000 population with a fair amount of industries could, Mr. Lucas judges, take care of the products of an economical plant.

### Cheap Gas For Cooking And Heating

"It has been the history in every case where by-product ovens have gone up in or near a city that there has been a cheapening of the gas because gas may thus be sold to a gas plant cheaper than they can make it, and still leave a fair price for the by-product plant."

The use of this cheap, surplus gas for domestic and industrial heating is the natural provision for its disposal. There is usually a residual tar product after the more volatile and more valuable constituents have been removed from the tar for the scrubbers, and this can be used economically as a binder in making briquettes from fine fuel, as such screenings.

After the hearing before the Senate committee, Mr. Lucas submitted a supplementary written statement, as follows:

### Large Plant Most Economical

"With further reference to the question as to how small an installation would be economical. It is well to remember that in common with most all manufacturing industries quantity production makes for cheapness of the product, and where possible, plants should be located at the largest centres. The coke coming into competition with anthracite can stand freight to the smaller towns and the gas can be carried in small mains under high pressure to any reasonable distance from the coke plant. One plant is delivering gas 120 miles away, so without the high operation costs necessary in small units it would be possible for the smaller towns to have all the advantages of gas fuel or coke equal to the large city where the plant was located.

"Contrary to a more or less popular conception a by-product coke plant is a very flexible installation. The production can be varied down to twenty-five per cent of the maximum without changing the quality of the product. The cost, of course, will be higher due to the same overhead and labour being charged against the small production. The quantity of saleable gas per ton of coal coked can be increased by upwards of forty per cent by heating the ovens by producer gas, and sending out all the gas made in the ovens. Or a still further increase can be arranged to take care of peak or winter loads by making water gas from some of the coke.

"**Loss in Handling.**—Once the coke is prepared at the plant for domestic use there is no loss in handling or breakage which would necessitate screening at the yards of the retailer.

"**Cost of Transportation.**—The railroads generally have set a rate on coke considerably higher than on coal, but this rate has been based on foundry coke which is the largest size and consequent low weight per cubic foot of car capacity. In the case of domestic coke, which is much smaller, there is very little void and cars can be loaded practically to their rated capacity, so that it would be reasonable to expect a lower rate.

"**Marketing.**—In a district like Montreal or Toronto, where domestic fuel has been 100 per cent anthracite, it would doubtless take a little time and entail considerable expense to introduce coke. It is however, from the standpoint of excellence and also from an economic standpoint the logical fuel, coupled with the gas which will be produced in such large quantities. Oil, peat and wood may be a more economical fuel in certain favoured localities, but none of them can be looked to as an effective or permanent cure for the present condition of depending on American anthracite.

"**Cost of Production.**—I have been asked this question and while I do not think it would be advisable to publish a balance sheet of operations which at the best would not be appreciable to all locations, I will state that domestic coke which is in every way and for every purpose superior to anthracite, can be manufactured and placed on the market at a price to compete with anthracite.

"**Government Aid.**—I have also been asked about Government aid for the building of a coke plant. I believe this would be advisable for the first plant at least until such an industry became established, but I do think that such aid should be preferably given to a company who would use Canadian coal.

The Schwab steel interests have lately purchased important zinc holdings in Oklahoma, on the express grounds of protecting their supply of zinc, of which the steel industry consumes 70 per cent of the annual production.

## SILVER PRODUCTION LINKED WITH GOLD AND BASE METAL MINING

In its current monthly review, the Mercantile Trust Company of California presents a study of silver production in the United States that shows clearly how it depends principally upon the amount of other metals produced. The following is extracted from the article:

What effect a reduced price for silver will exert upon business conditions in the western states cannot accurately be foretold. In a consideration of this question, however, it is well to bear in mind that metal mining in the western states as a group can not now influence the ebb and flow of good and bad times to the extent that it did in earlier years.

Although as an industry metal mining has grown greatly, its relative importance has lessened as agriculture, lumbering, petroleum production, and allied industries expanded more rapidly.

For instance, gold mining was once the principal, and for a time almost the sole, industry in California. Nowadays such an unromantic item as the hay crop of California annually exceeds the state's entire yearly output of the precious metals.

Building stone, cement, brick — lowly products dug from the earth for structural purposes — now annually exceed in California the state's entire yearly output of precious metals.

There are, of course, districts and communities in which metal mining is the principal, and almost the only, industry. But even among such districts there are few in which the price of silver alone is the controlling influence.

Silver is mined principally in conjunction with other metals. In many districts it is almost entirely a by-product and the annual output of silver in such districts is governed not by the price of silver but by the price of copper, or the price of lead, to the production of which the production of silver is largely incidental.

The big jump in silver production in Utah in 1922, was in large part a reflection of the improvement in lead. In that year lead sold at an average of 5.7 cents a pound compared with 4.5 cents in 1921, while Utah's output in 1922 was 67,000 tons, an increase of 50 per cent over the preceding year. About half the silver mined in Utah comes from lead ores.

In Idaho between 90 and 95 per cent of all silver produced is mined from lead and lead-zinc ores. The price of lead and zinc, as well as the price of silver, therefore have a direct and important bearing on the amount of silver mined.

A heavy decrease in the output of lead and copper in Montana in 1921 was mainly responsible for the sharp decline in silver production that may be noted in that year on the chart. Over half the silver from Montana is mined from ores in which lead and copper predominate.

Montana's output of silver in 1916 — a year of good copper prices — was over 16,000,000 ounces although the average price for silver was less than 66 cents. Two years later, also a good copper year, Montana's output of silver was about the same as in 1916 although silver meanwhile had risen to an average price of a dollar an ounce. But in 1921 Montana's output of silver was only six million instead of sixteen

million ounces, although a minimum price of \$1.00 an ounce for silver throughout that year was guaranteed by the Pittman act. The prices of copper and lead, and not the price of silver, caused the drastic reduction in silver output.

In the same way higher prices for copper and lead in Montana in 1922, resulting in increased production of those metals, carried silver production up again despite the fact that the price of silver was unchanged.

A somewhat similar story may be told of Arizona. Far more than half the silver produced there comes from copper ores, and 10 or 15 per cent from lead ores. The year 1921 was one which registered a heavy drop in both copper and lead production, with a noticeable decrease in silver as a result, although the price of silver was held at \$1.00 an ounce.

"The total number of silver mines and the total production of true silver ores are both very small," says the United States Geological Survey.

According to the same authority nearly all the ores mined for their precious metal content are primarily gold ores.

Nearly all the silver in Nevada comes from ores mined for their gold and silver content. The total recovery of silver in the whole country from this kind of ore was greatest in 1913, when the output from the Tonopah district of Nevada was at its height. In that year Nevada supplied over 54 per cent of the silver recovered from ores in which the precious metals predominated. Since then the percentage has steadily dropped, until in 1921, the latest year for which figures are available, the proportion was only 27 per cent.

It is interesting to note that in 1919, when silver prices were higher than they had been since 1882, silver production was at its lowest point for many years in three of the places where it comes mainly from precious-metal bearing ores — Nevada, California and Alaska. In all three of these gold production was at a lower ebb than it had been in any previous year since 1905.

Although the current commercial price of silver is now, and for many months has been, considerably lower than the guaranteed Mint price of a dollar an ounce that producers of domestic silver have enjoyed, it does not necessarily follow that the production of silver in the western states will decrease in the same proportion that the price of silver decreases. It is interesting to note that there was a large production of silver in many years when the average price of silver was far less than \$1.00 an ounce.

The average production of the eleven western states and Alaska combined was in the ten years preceding the war approximately 59,000,000 ounces. And in those ten years the average annual price ranged from 68 cents at the highest to as low as 52 cents.

In startling contrast to this are the years 1919, 1920 and 1921 when the price of silver was either far above a dollar or was guaranteed not to go below a dollar. In not one of these three years did the silver output of the group equal the average of the preceding years when prices were low.

Producers, refiners and sellers of silver in the United States control between 85 and 90 per cent of the world's production, according to estimates of the Geological Survey, but the price depends principally upon the demand from foreign countries.

## THE EMPIRE'S RESOURCES IN THE RARER METALS

### A Wide Field Open For Investigation.

Professor G. F. Morgan, head of the Chemical Department of the University of Birmingham, recently delivered an address on "The Empire's Resources of the Less Common Metals," which is reported in the *Chemical Trade Journal and Chemical Engineer*.

Professor Morgan referred to the Empire's resources in the precious metals, gold and silver, and also to the light metals, aluminium, magnesium, and beryllium, which are of special interest in the production of light alloys. Ultra light alloys are now being produced by the Magnesium Co., Ltd., of Wolverhampton. The metals of the less common earths are utilised chiefly in the form of their compounds. Barium and strontium preparations are largely derived from British sources, and the world's requirements for thorium and ceria employed in the incandescent mantle industry are largely supplied from the extensive Travancore deposits which will meet the demand for many years.

### Tungsten, the Platinum Metals, and Cobalt.

The favourable situation of the Empire in regard to the supply of tungsten minerals should place us in a premier position for manufacturing tungsten steel, but nevertheless before the war Germany controlled two-thirds of this production, the importation of German tungsten into this country having an annual value of £300,000. He regarded the production of tungsten steel as one of the great triumphs of modern metallurgy. Zirconium was cited as an instance of a metal which has so far been examined chiefly by German and American chemists, the English contribution to this branch of mineral chemistry being very small. There is a world famine in regard to the valuable metals of the platinum group owing to the partial failure of the Russian supply. These metals have been detected in many parts of the British Empire. Tasmania has furnished osmium and iridium, whereas the Sudbury nickel-copper ores of Ontario have yielded notable quantities of platinum and palladium. Cobalt is a metal with a future, coming into use now as an alloy metal instead of being restricted, as it was until recently, to use in combination as a pigment colouring material. Cobalt which is produced annually to the order of about 400 tons confers hardness and durability on aluminium.

The possession of this varied assortment of mineral wealth, said Professor Morgan, carried with it the obligation to utilise this heritage to the best advantage of humanity. If the present possessors fail in this respect, sooner or later the task will be undertaken by others.

### The Magnesium Position

Referring to magnesium, he pointed out that the metal is permanent under ordinary atmospheric conditions, especially when free from impurities. Minute quantities of such foreign substances as alkalis or chlorides cause local granular corrosion. The metallurgy of magnesium depends on electrolytic processes, and considerable progress in its isolation has been made in the United States. The sudden drop in the number gives a solution containing sodium beryllium fluoride of producers and in the output is due to the competition of the German product. Germany controls a large portion of Australian magnesite, and owing to the depreciated currency it can sell in any market in spite of the import duties.

## Research on Beryllium Production

On the subject of beryllium, Professor Morgan had something interesting to say. Owing largely to the headway has been made in the isolation of beryllium, although the physical constants of this metal show that it would be a valuable aid in the production of light alloys. The commonest mineral, beryl, is an acidic silicate of beryllium and aluminium, occurring both in the old world and the new. A well-known deposit exists at Limoges in France, and considerable quantities have been noted in New Hampshire, where beryl crystals of enormous sizes up to 2½ tons occur native. Within the British Empire there is a small unexploited deposit in Glen Cullen, Co. Dublin. It is also found in the former German Colony of S. W. Africa. Hitherto only small quantities of beryllium metal have been produced. The first difficulty encountered in the metallurgy of beryllium is the separation of beryllium from alumina.

Beryl is not appreciably attacked by the common mineral acids. It is opened up, however, by fusion with caustic alkali, subsequent treatment with dilute sulphuric acid precipitating silica. The filtrate contains beryllium and aluminium sulphate, and if the alkali used in the fusion contained potash, a good deal of aluminium sulphate crystallizes in the form of potash alum and is thus separated. The beryllium remaining in solution is partially separated from the remaining aluminium by taking advantage of its solubility in ammonium carbonate, this reagent precipitating aluminium hydroxide. By diluting and boiling the solution, hydrated beryllia is precipitated and converted into the basic acetate, a compound of considerable stability which although only sparingly soluble in water, has the remarkable property of dissolving in such organic solvents as acetone, chloroform, benzene, etc. This beryllium derivative has a definite melting point and when pure can be sublimed without decomposition. These singular characteristics render it useful in the final separation of beryllia from alumina.

Two other processes have been tried with good results at Birmingham University by Mr. Hedley. In one process beryl is heated with hydrogen fluoride and ammonium fluoride until the silicon is volatilised and the residue contains the fluorides of beryllium, aluminium, and iron. The second procedure consists in heating the finely powdered mineral with sodium silico-fluoride. The product on lixiviation with water gives a solution containing sodium beryllium fluoride only, the other constituents remaining as sparingly soluble products. Whatever process is employed we find that the final purification is best effected through the basic acetate.

We are still only on the threshold of the metallurgy of beryllium. The purified acetate must be converted into oxide and fluoride, when, by an electrolytic process akin to that employed for aluminium, the metallic beryllium is isolated. Even a moderate supply of beryllium or its alloys with copper and other metals would be an aid in aeroplane and airship construction.

Aluminium is the only fairly plentiful metal of the light metal group; some of the others, such as scandium, gallium, indium, and thallium being excessively rare. Yttrium and lanthanum belong to the rare earths comprising some 18 elements of which certainly two have met with industrial application. These are

thorium and cerium, both of which are derived from the mineral monazite.

### The Future of Titanium and Zirconium Compounds

Titanium in the form of its oxide (rutile) or as the ferrous compound, ilmenite, is widely diffused and is among the more plentiful elements of the earth's crust. There is as yet no commercial method for producing elemental titanium. Difficulties arise owing to the chemical activity of the element and its high melting point (about 1,800° C.). The most important use of titanium lies in the production of ferrotitanium alloys. These alloys are used as deoxidisers, oxygen and nitrogen scavengers and not as alloying materials. Before the war there were 15 manufacturers of titanium alloys in Germany, 3 in Great Britain, 2 in France, and several in Sweden and Switzerland. Titanium,  $TiO_2$ , is used in pigments and in glass.

Zirconium and its compounds are a worthy subject of chemical research. Mr. Bowen, who has undertaken an experimental study of zirconium and its compounds, has preceded his investigation by a thorough and complete search through scientific literature. He was mortified to find that nearly all the research work on zirconium has been carried out by American or German investigators. The value of zirconia as a refractory material has been clearly demonstrated. It has been employed in making crucibles, muffles and combustion tubes which are gas tight up to 1,000° C. Zirconia crucibles have been used to melt pure iron, platinum, and tungsten alloys. Zirconia linings for the hearths of steel furnaces are very durable. It is also used to produce opacity in glasses and glazes. In medicine it has been substituted for bismuth nitrate as a means of taking X-ray observations of the alimentary tract.

### USES OF PULVERIZED LIMESTONE

In the progress of a study of methods of utilization of waste rock at lime-plant quarries, being conducted by the United States Bureau of Mines, it has been found that limestone pulverized to a much finer grained form than for agricultural use is finding wide application in various products. Small quantities may be added to stock food as a bone builder. A dust approximately 80 percent of which will pass a 200-mesh screen is the most widely used filler in road asphalt surface mixtures, though slate flour and Portland cement and hydrated lime are used to some extent. Ground limestone is used to a limited extent as a fertilizer filler. It has the advantage over inert fillers in that it has valuable properties as a soil conditioner. Very finely pulverized limestone may be used successfully as a whiting substitute in certain classes of rubber, paint and other products. It is essential for such uses that it be very finely ground and uniformly sized so as to exclude all comparatively large-sized grains. In general limestone flour that will successfully meet the requirements of fillers of a type like whiting or china clay should approximate 300-mesh size. Few lime-plant quarries have the equipment for grinding or sizing to this degree of fineness, and have, therefore, been able to utilize this promising field of application.

### ORES OF ALUMINIUM

Minerals containing aluminium are abundant, the most widely distributed being the clays. There are only two, however, thus far of consequence, commercially, in the production of the metal: bauxite (to which may be added the related, hydrated oxides, hydrargillite and diaspore), and cryolite. Cryolite is found in commercial quantities only in South Greenland, and was formerly the only ore of aluminium used, being still employed as a flux in the extraction of the metal. Bauxite has been, for some years, the most important source of aluminium and its salts. Its color varies from gray to brown, its composition ranging usually between the following limits:  $Al_2O_3$ , 30%-60%;  $Fe_2O_3$ , 3%-25%;  $SiO_2$ , 0.5%-20%;  $TiO_2$ , 0.0%-10%. Besides its reduction to the metal, bauxite is also utilized in the manufacture of aluminium salts, refractory bricks, alundum (fused alumina) for use as an abrasive; and in the refining of oil (stated to be of growing importance). The most important producing countries, both of bauxite and the metal, are the United States and France, the former yielding more than 60 per cent of the world's output.

### NICKEL IN AUSTRALIA

The copper ores of Australia characteristically contain a small amount of nickel, from 0.10 per cent upwards. A writer in "Chemical Engineering and Mining Review" proposes to recover part of this nickel by a simple method. As the presence of more than 0.25 per cent nickel in fine refined copper is penalised, and as blister copper for electrolytic refining must not contain more than 0.50 per cent nickel, the amount is reduced to these limits by running slags that contain, in addition to several per cent nickel, a much larger proportion of copper. It is proposed to run this slag, when it has accumulated sufficiently, in the blast-furnace with ore to give a blister copper carrying 10 to 12 per cent nickel. This should be melted in a reverberatory, where the copper will melt while the nickel will oxidise and float as a pasty mass, which can be skimmed off as a dross that will contain a comparatively small amount of copper. Pure nickel can be made from this by electrolysis, using a special container for the dross, which cannot be cast into plates.

### POSITION OPEN IN OTTAWA

Applications will be received, on forms available at the usual places, by the Civil Service Commission up to June 21st for the following position in the Mines Branch: 5435 — An engineer in the Division of Fuels and Fuel Testing, at an initial salary of \$2,100 per annum, subject to annual increase and whatever bonus may be provided by law. The duties will be to assist in both field work and laboratory investigations on Canadian fuels.

Pure antimony metal and manufactured antimony compounds are of considerable importance as pigments in the ceramic industry. The most important use of the metal, commercially, is in various alloys, particularly type-metal (with tin and lead), babbitt (with tin and copper), and Britannia metal (with tin and copper).

## THE USES OF ZINC

Zinc is one of the most largely used metals says the *Bulletin* of the American Zinc Institute. Before the war more zinc was produced than any other metal, except iron and lead. In fact the uses of the three metals, zinc, copper, and lead are about equal in quantity. The reason why so few people realize how much zinc is used is simple: Zinc seldom comes to the consumer alone, or under its own name.

The largest use of zinc is in making galvanised iron, which is iron coated with zinc by dipping it in a bath of melted zinc. This gives a coating which protects it from the action of the weather, and if properly done, increases its life manifold. Many people know that "galvanising" is coating with zinc, but as the product is known as iron they do not realize that it owes its value to the zinc coating.

The next largest use of zinc is in making brass, which is an alloy of zinc and copper, containing from 5 per cent to 50 per cent. of zinc (usually 25 per cent. to 33 per cent.), frequently with the addition of small quantities of other metals. The properties of the alloy depend on the proportions of the different ingredients. By properly varying the constituent alloys, a great variety of strength, hardness, and ductility can be obtained, and these make the brass suitable for an infinite number of purposes.

Sheet zinc is used to a fairly large extent, but not nearly as largely as its good qualities deserve. On the continent of Europe zinc sheets are the most common metallic roofing.

All of the common metals are attacked by air and moisture, but the results of this attack vary greatly. Zinc, however, when exposed to the weather, becomes covered by a thin, hard and closely adherent crust of basic carbonate of zinc, which completely protects the metal beneath. The coating, being hard and adherent, does not stain other objects. In practically all cases where galvanised iron is used sheet zinc would be better. Its first cost would be higher, but its much longer life would more than compensate for this.

Zinc roofs have been in use in Europe for about 100 years, and some of the original roofs are still in place, and in good condition. A few zinc roofs were put on by the Lehigh Zinc Co. when it operated a rolling mill in Bethlehem some time between 1860 and 1870. These roofs were in perfect condition when the buildings were torn down, after 50 years, and had never required repairs and were never painted.

For flashing, gutters, and leaders, zinc is an ideal material, if a suitable grade of zinc is used, and is properly installed. There are several grades of zinc on the market, containing varying amounts of impurities. For most of the purposes for which zinc is used these impurities are not injurious in the quantities in which they occur in commercial zinc, but they all make the zinc harder and more brittle, especially at low temperatures. As the sheets used for flashing, gutters, and leaders must be bent sharply and often in cold weather, only the purest zinc should be used for these purposes.

Zinc castings are used to an extent that very few realize, as they are nearly always plated with some other metal, and usually are sold to the consumer as bronze. All sorts of ornamental objects, electric fittings, lamps, jardinières, ash receivers, ink stands, etc., are made in this way. Zinc is very suitable for such purposes, as it makes sharp and accurate castings, which can be plated with any metal.

Zinc is also used in separating silver from bullion. In a great many cases silver and lead occur in the same ores, and when these ores are smelted the resulting metal or bullion contains both the lead and silver—a ton of bullion containing only about 100 to 200 oz. of silver. The easiest

way to separate them is to add some zinc to the melted bullion at a temperature high enough to melt the zinc. The mixture is then cooled slightly, when the zinc and silver freeze together, and can be skimmed out. The result is that the silver is recovered in combination with a very small amount of zinc, from which it can be easily separated by distillation.

Still another form in which zinc is produced is a fine powder, called zinc dust, largely used in dyeing and in the manufacture of dyes, in recovering the gold extracted from ores by the cyanide process, in flashlight powders, and in other products. During the war a great deal was used in shells to give a cloud of white smoke to mark where the shell struck.

In addition to its use as metal, a great deal of zinc is used in making salts and pigments. The most largely used salt of zinc is the chloride, which is used in preserving timber from rotting and in making fibre ware.

The two zinc pigments are the oxides, either commercially pure oxide of zinc, or mixtures of zinc oxide and basic sulphate of lead (known as "leaded oxide"), and lithopone, a mixture of sulphide of zinc and sulphate of barium.

Zinc oxide is one of the most largely used pigments, and is used in all of the better enamel paints, flat wall finishes, and most of the mixed paints. It is of pure and brilliant white, and does not darken or change colour on exposure, nor does it chalk and rub off. Experience has shown that a mixture of pigments gives a better paint than any single pigment. Zinc oxide, on account of its good and uniform colour and permanence, is the most valuable single ingredient of these mixed paints. It is also used in the manufacture of enamelled cloth, oilcloths, and linoleums.

The leaded oxide is not of quite so good a colour as the pure zinc oxide, but is an excellent pigment, and is largely used in tinted paints.

A very pure variety, known as pharmaceutical oxide, is made by special processes from selected materials, and is used in medicine, for face powders, and other purposes, where extreme purity is necessary. During the war large quantities of it were used under the name of "sag paste," as a protection from and cure for mustard gas burns.

Zinc oxide is very largely used in the manufacture of rubber goods. Pure rubber alone is useless for such mechanical purposes, as automobile tyres. A tyre of pure rubber would wear out in less than 100 miles, but when reinforced by a pigment such as zinc oxide, this can be increased to 8,000 or 10,000 miles. An automobile tyre may contain as much as 25 per cent. of its weight in zinc oxide.

Zinc oxide has been used successfully as a rubber filler ever since the development of rubber compounding. This is due principally to the fact that the zinc oxide particles adhere firmly to the rubber and increase the strength and wearing properties of the compound article. Then, again, the life of the rubber is prolonged rather than shortened by the use of this pigment.

Lithopone is a comparatively new pigment, and its use is increasing very rapidly. It is made by mixing solutions of zinc sulphate and barium sulphide in the proper proportions. The resulting product is a combination of zinc sulphide and barium sulphate, very closely bound, and of much better hiding power and colour than can be made by mixing the same two salts separately made. Lithopone is a very brilliant white, and is permanent in colour, if properly made. It is very largely used in making the popular flat wall finishes and other interior paints. For outside paints lithopone alone is not satisfactory, but a mixture of it with other pigments gives good results. It is also used

in making enamelcloth, oilcloth and linoleums. For certain grades of rubber goods it is largely used, as it gives an excellent colour, with good strength, and other desirable qualities.

### THE HEALING POWER OF BUSINESS

In 1921 more than 3,000,000 tons of coal were shipped from the United States to England, and coals were literally carried to Newcastle and unloaded there. The following year slightly over 3,000,000 tons of coal were shipped from the United Kingdom (some of it from Newcastle) to the United States. Now, in the spring of 1923, the last of the incoming shipments of coal from the United Kingdom again meets the first of the outgoing cargoes of coal from the United States to continental Europe, and the economist, perhaps, throws up his hands in despair at the unwarranted waste of carrying these millions of tons back and forth across the sea.

But instead of assuming such an attitude he should give thanks for the saving grace of the trader's flair for business, which brings the things that humanity wants to the place where it wants them in spite of "strikes, war, pestilence, acts of God, or force majeure."

All this is nothing new, but the thing that is new is the fact that the healing currents of business now flow far more swiftly than in the past to fill a want created anywhere in the world. Inflation and deflation, prosperity and hard times tread more quickly on each other's heels that was their wont in days gone by. This is because the means of communication grow ever better and draw the world closer together.

Thus it behooves the international trader of to-day to keep his eye on the far horizon, for the far horizon is, after all, not so very far away. —Commerce Reports.

### A BIBLIOGRAPHY OF COLLOID CHEMISTRY

The National Research Council, Washington, has recently issued a colloid bibliography in mimeographed form. The author, Dr. Harry N. Holmes of Oberlin College, Chairman of the National Research Council Committee on the Chemistry of Colloids, intends this edition to be preliminary to a more comprehensive one. Yet it is a book of 135 pages containing 1,800 references on 106 topics. All the references are classified and many are accompanied by brief reference as an aid in deciding on their relative importance. This book may be purchased from the Washington office for \$1.00.

Among the classified groups are Absorption, Asphalt, Baking, Bicolloids, Capillary Analysis, Casein, Cellulose, Cellulose Esters, Cements, Clays and Soils, Cleansing, Coagulation, Dialysis, Emulsions, Filtration, Flotation, Foam, Flour, Fogs, Gels, Gelatins, Glass, Glues, Gold, Gums, Hydration, Indicators, Jellies, Lubricants, Milk, Paints, Peptization, Petroleum, Photography, Protein Swelling, Protection, Rubber, Sewage, Silver, Soap, Sulfides, Surface Tension, Tanning, Ultramicroscope, Viscosity, and Waterproofing.

The theoretical and industrial importance of colloid chemistry is now admitted without question; in fact it links together the sciences of chemistry, physics, zoology, botany, geology, medicine, agriculture and even astronomy, when that science deals with comets' tails. Few are the industries that do not have colloid problems to solve. The average citizen is surprised to learn that his own body is colloidal in composition, that his digestive processes are governed by colloidal rules of action and that the bacteria of disease are of a colloidal degree of

dispersion. And he is astonished to learn that but for the colloidal absorption of calcium phosphate from the blood stream by his bony cartilage he would be a mere spineless jellyfish. As colloid chemistry is surface chemistry, it is of importance to this same average citizen to know that the total surface of his blood corpuscles is about one acre.

### THE COLOR FACTOR IN TALC

A very pure white is demanded by many consumers of talc, but no standard, accurate method of detecting slight differences in color has been devised, states R. B. Ladoo, mineral technologist of the United States Bureau of Mines, who has completed a study of the mining, milling and uses of talc. Practically all talc producers make a rough comparative test by the unaided eye, usually comparing tales to a sample taken as a standard, which varies for each producer and consumer. The talc is either placed in little heaps or is spread out flat with the finger or a knife, on the hand, or on blue or white paper. Probably the best the best method now in use consists of forming two small piles of the material used as a standard and of the talc to be tested, pushing the heaps close together and flattening them with a spatula so that the contact between the heaps is a smooth straight line. If the tales are then wet with a few drops of turpentine, slight differences in color may be detected; but even this method is not satisfactory, as no standard samples are used in common by the whole industry, and differences in light and in human perception give different results. Often the accurate determination of slight color differences is of utmost importance, for color is not only an index of value but frequently is an indicator of proper methods of grinding. Poor color is not always due to impurities, but may be due to insufficient or improper grinding. Thus a yellow hue in a tale was attributed to iron, but microscopic examination proved that finer grinding would eliminate most of the objectionable tint. Finer grinding of many tales improves the color. A uniform and standard method for the determination of color should be devised and adopted.

### LIGNITE CHAR

At the spring meeting of the American Institute of Mechanical Engineers, to be held in Montreal, O. P. Hood, Chief Mechanical Engineer of the United States Bureau of Mines, will present a paper on "Lignite Char,." This fuel is made in single ovens where moisture is first driven off and then volatile material distilled, leaving the fixed carbon, much shrunk from its former size, as a fairly porous material with much the same analysis as anthracite coal. It ignites readily and burns freely. It can be briquetted to give a domestic fuel unsurpassed in qualities; but the char itself is a satisfactorily domestic fuel if handled properly. The distilled gases are used as fuel in the kiln, which is somewhat similar to an open-top lime kiln. One ton of char is produced from about 2½ tons of raw lignite.

The new mill of the New State Areas, South Africa, designed to handle 50,000 tons a month, is nearing completion. It is the first mine on the Rand to discard stamps in favour of rolls.

# THE MINING DISTRICTS

BY THE JOURNAL'S CORRESPONDENTS.

## NORTHERN ONTARIO

**Porcupine.**—Production at the Dome is stated to be at the rate of over \$400,000 a month, the daily tonnage going to the mill being approximately 1,250 tons. The annual meeting of the shareholders is to be held shortly, and it is understood that some of them will insist on a definite policy as regards dividends. While the President has stated that in July the dividend will be doubled, it is not certain that all the directors are in favour of this policy. Proxies are being asked for in the names of Ernest C. Whitbeck and Jacob E. Rosenberg, both of Rochester, who are said to be large shareholders. While the proxies are not being solicited with the view of ousting the present directorate, it is desired to have these two gentlemen on the board so that better representation may be given to certain large shareholders. The recent raid on the stock, which resulted in a severe drop in prices, will, no doubt, give a certain impetus to this movement.

The Hollinger has declared the regular four-weekly dividend of 1%, payable on June 18th, to holders of record May 31st. The company is continuing to increase its production. Practically all the available power in Porcupine is being used by the three big companies.

The Porcupine mines now have the largest number of workers in their history and these are being added to daily. The strike talk appears to have pretty well died down and it is reported that of approximately 4,000 men employed at the mines only 532 cast ballots at the recent strike vote. Of this number about 400 voted for a walk-out, or only about 10% of the employees. The Union officials have announced that they will extend the privilege of voting to the non-union members, but as less than half the union members voted, it is not anticipated that the non-union members will make as good a showing.

At the Night Hawk Peninsular approximately ninety men are employed and work on the construction of the mill is well under way. Underground development continues to be promising, and the property looks like a profitable producer.

An interim report issued by the Porcupine-Davidson Gold Mines, Limited, states that a large amount of diamond drilling has been done which indicates the existence of 700,000 tons of ore, averaging \$9.25 a ton. This ore is reported to exist between the 500 and 1,000-foot levels, while above the 500-foot level the estimated ore reserves are approximately 330,000 tons of \$11.00 ore.

This makes a total of over \$10,000,000 estimated ore, most of which is based on diamond-drill results. It is well to point out, however, that none of the producing mines of Porcupine ever estimate ore with no further information than that obtained by diamond drills. The company is commencing the sinking of a three-compartment shaft, which will be continued to the 1000-foot level. A temporary head-frame is being erected and a steel head-frame is on order. Plans for the 500-ton mill have been prepared and it is expected that construction

will be commenced in the near future. The company has cash assets of approximately \$550,000.

At the Clifton Mines a diamond-drilling campaign will be undertaken on the 200-foot level in order to gain further information before sinking a new shaft.

**Kirkland.**—It is reported from Kirkland lake that two veins, carrying substantial values, have been intercepted on the 450-foot level of the Montreal-Ontario.

**Larder.**—Reserve will shortly offer 500,000 shares of stock at sixty cents a share, subscriptions to close June 15th. The proceeds of the new issue will be used to continue development work and to prepare the foundations for a mill. It is expected that when construction work on the mill is commenced a further issue of stock will be made.

**South Lorrain.**—There is much activity in the South Lorrain district, and several new deals have recently been reported. A deal has been negotiated for the sale of the bed of Trout Lake, which lies South of the Keeley. A shaft has been sunk on the shores of the lake to a depth of 275 feet, and it is probable that this will be continued. J. H. Rattray is in charge of a group of claims, on which work is being commenced. The Lorrain Consolidated has shipped a mining plant to the property and as soon as this arrives underground work will start.

The Mining Corporation continues to obtain a substantial production and in April shipped 183,000 ounces. Shipments in May were small on account of the bad roads, which made it almost impossible to get the ore out. So far the company has produced over 1,000,000 ounces from one shoot on the Woods vein alone, and during the first four months of the present year the company's production from the South Lorrain property has been approximately 750,000 ounces.

**Cobalt.**—The report of the Peterson Lake for the year ending April 30th shows an operating loss of \$24,472. The profit and loss balance has been reduced to \$77,286. The balance sheet shows liabilities of \$96,000 and current assets are figured at \$70,000, which includes ore reserves of \$49,000. During the early part of the year the Dominion Reduction Company mill treated old tailings on a joint account with the Peterson Lake. However, the silver content proved to be low, and the expense of overhauling the mill was heavy, so that operations resulted in a loss to Peterson Lake, and the property is now under option to the Mining Corporation.

**Rouyn.**—La Rose Mines has taken an option on three claims in Rouyn township and has sent in a gang of men to prospect them. The Lyman-Quebec syndicate has also sent in a crew to start exploration work. The diamond-drill that has been operating on the Hammill option has been moved over to the Noranda Mine claims, where it will probably be kept for the rest of the summer. So far, work on the Noranda has been confined to surface exploration. Transport companies have been formed to operate trucks and motor boats into the district, so that travelling is now comparatively easy.

## NOVA SCOTIA

**Wabana Activities**—The Wabana iron ore trade, while not as promising as last year, is nevertheless fairly active. Whether this activity will continue throughout the year, will soon be known. Last year the German trade took 750,000 tons of ore, and it was found so satisfactory and so suitable for steel production that an offer was made the Empire Steel Corporation for the trade of this year. The occupation of the Ruhr district by France dislocated trade and affected Wabana production seriously. In the middle of January of this year the Wabana mines were closed down and the outlook seemed black; but the Premier of Newfoundland, sizing up the situation saw that something had to be done to help the workmen of his country. He therefore visited President Wolvin of the British Empire Steel Corporation and an arrangement was entered into by which the mines were to be re-opened and kept running during the months of March, April and May, giving employment to 1,600 men. The company on their part were to have the ore export tax remitted during 1923. Since this agreement was drawn up, conditions in Germany have not improved radically, and possibly the shipment to that country will not exceed 150,000 tons. However, other orders have been received from the United States and from British firms, and although smaller, not exceeding 125,000 tons in all, they form a nucleus for future business that may develop during the present year. Conditions are not stable and the maximum output capacity is not taken care of by present contracts, and whether the force and output may have to be reduced will be known some time during this month.

At present four mines are in operation, the daily output being 3,700 tons. Approximately 800,000 tons of ore are in the stock piles, and if no new business is forthcoming, some of the mines may have to be closed down and ore shipped from the piles. The Sydney Smelting plant will take about 400,000 tons during the year. Three boats are already in the business, one with a capacity of 10,000 tons and two with capacities of 8,000 tons.

**Newfoundland Labour Conditions**—Newfoundland in the past furnished much labor to the Cape Breton collieries. But during the last two years, labor conditions have been very much depressed and it has been estimated that fully 25,000 people have left Newfoundland for the United States and Canada to establish homes for themselves in these countries.

The fisheries have been, relatively, a failure, no profit having been made by the fishermen. Indeed, it is a common statement among the fishermen that the more work they do, the deeper they become involved in debt.

At present, the Humber power plans are being completed, and work is going ahead on the large plant, on which men will find employment during the summer.

The Anglo Newfoundland Company has taken over the sulphite pulp plant at Alexandria Bay and have a problem of railroad construction and plant extensions that will give employment to 1,000 men during the rest of the season.

The plant at Grand Falls, with auxiliaries, will employ 1,500 men.

The British Empire Steel activities in Newfoundland will employ not less than 2,200 men, including the force at the limestone quarries at Port Au Port. This makes

a total of 6,300 workmen, which is about the limit of industrial labor in Newfoundland, so that the Cape Breton industries can expect little labor from this source during the present year.

The quarries at Port Au Port will give employment to 350 men for the summer months. About 300,000 tons of limestone will be shipped to Sydney.

**Gull Pond Copper**—The recent diamond-drilling carried out at Gull Pond, Newfoundland, has proved the presence of a very large deposit of copper ore. At present a body of ore 2,200 feet long, 77 feet wide and 1,200 feet deep, carrying high values in copper has been proved. The owners are making arrangements to finance further development, and it is understood they have been successful in raising the required funds. This new copper district will be accessible to the Humber power development and progress should be rapid after the construction of the Humber plant.

A second copper deposit, on the west coast of Newfoundland between Bonne Bay and Bay of Islands, also gives promise of developing into a large producer. Very little work has been done on this property, but the ore is very rich and seems to rival in quality that of the Little Bay deposit.

**J. L. Lewis Sends Commission**—A commission of four U. M. W. officers has been sent by the International headquarters to investigate and report on labor conditions at the Collieries of Nova Scotia. While nothing much is being said at present by the members of this commission, there is enough known of the differences existing between the District and International headquarters, to give a fair idea of the scope of investigation.

The open hostility of the executive of District 26 to President Lewis and their favor of Alexander Howatt has not been concealed. International headquarters has been placed in a most unfavorable light before the workmen on more than one occasion. They have been blamed for withholding funds to enable the district to conduct a campaign against the coal companies. At the investigation before the International Board, President Lewis, in reply to President Livingstone, stated that \$10,000 had been sent into Nova Scotia, when it was needed last year. The executive, however, believe that funds collected for Union purposes should not be used to help along a political campaign of the Workers' Party or to run a newspaper like the *Labor Herald*, which represents this party and nothing else. If the money used had been applied to its proper purpose, there would be no need of financial aid from the United States.

Further, the district was advised by President Lewis last August, when the strike was on, to leave the maintenance men at work. These orders were disregarded and the men were withdrawn from the pumps, boilers and power-houses. The lower lifts of some of the collieries were flooded and much damage was done at that time. But the greatest harm came from the fact that the district was rebellious and failed to comply with the instructions of headquarters.

The election of officers in the district has become a species of political campaign, and the time set by the constitution to hold such elections is disregarded. If some dispute of wages is on, the executive of the district, believing they can win if the dispute is made an issue

bring on the election. In this way the main issue is lost sight of and the organization is used to suit the vaulting ambition of its officers.

The Truro convention, with its resolution to join the Red Internationale, came as the climax of a policy long in the mind of Secretary McLachlan.

While the resolution was passed by the convention, many of the delegates did not take it seriously; but it sufficed to re-elect the officers and to prepare the way for the demonstration held on the first of May in Glace Bay, under the Red banner. The attempt, however, to join up with the Red Internationale estranged the Cumberland and Pictou locals, and they have not ceased since that time to protest against the insane action of their leaders.

The latest development is the forming of the Progressive Workers' Party. Under this name, the locals were lately circularized with the purpose of sounding them on their attitude towards the International Union. If it developed that the Workers' Party showed strength, the International was to be given short shrift. The locals, however, were not blind as to what was taking place, and many of them voted against the Progressive Workers' Party. Nor are they in favor of the four-day week. They are now in the mood to settle down and to be finished with all agitation, which robs their homes of contentment. It is in this state of mind the Commission will find them and the survey of the field by these four Americans should do much good. It cannot possibly do harm.

### BRITISH COLUMBIA

**New Tunnel for Premier.**—A new tunnel, which is expected to be driven a distance of 2,400 feet and which will measure 8 x 9 feet, has been started from near the international boundary line on the property of the Premier Mining Co. Its purpose, it is said, is to give an additional 500 feet depth on the veins being worked and to develop an extension southwest from the present workings that was located by diamond drill. It is reported, unofficially, that a second mill will be constructed near the portal of this tunnel. The Premier camp is being provided with a new bunkhouse containing 100 rooms, and an apartment house and assembly room also are proposed.

**Stewart.**—The Stewart Consolidated Gold Mines Ltd. has been formed to take over some sixty mineral claims in the Bear River section of the Portland Canal District. Capitalization has been placed at \$3,000,000 and it is said that about \$100,000 will be spent on development this year.

F. N. Cronholm E. M., of the Cronholm-Bartholf Mines Ltd., owners of the Bromide Group, Chickkamin Glacier, Salmon River, and E. G. Riebe, consulting engineer of the Silver Bell Mining Co., are recent arrivals at Stewart. They state that their respective properties are to be energetically developed this season.

**Atlin.**—The Engineer Mine, Atlin, one of the most promising of the province's lode gold properties, again is the subject of litigation. Robert E. Williams, Milwaukee, and Horace K. Williams, Los Angeles, nephews of the late Mrs. James Alexander, who, with her husband, was drowned when the steamer "Princess Sophia" was lost with all hands in October, 1918, are suing J. A. Fraser, administrator of the late Captain Alexander's estate. They claim that as next of kin to Mrs. Alexander they are entitled to shares in the estate that includes the Engineer Mine. As there are a number of complex questions to go before the court, such as who

died first, the Captain or Mrs. Alexander, did Mrs. Alexander by marriage acquire a dower interest in the property, and what is the effect of Captain Alexander's will made before his marriage bequeathing all his property to the late A. I. Smith of Philadelphia who financed his operations, it is likely that the legal argument will be extended.

**Rossland.**—First indications of the promised new activity at Rossland are apparent in the action of the Consolidated Mining & Smelting Co. in starting work on a crushing plant at its mines in that camp. The foundation is being excavated on what is known as Centre Star Hill. The purpose of the crusher is to permit the treatment of the ore at the mines before shipping in order to economize on handling at the smelter.

**Canada Copper Co.**—The announcement from New York that the Granby Consolidated Mining & Smelting Co. has taken over the Allenby Copper Co. (known locally as the Canada Copper Co.), and that the mine and mill at Allenby will forthwith be opened up, has been received in British Columbia as one of the most important western Canadian mining developments in years. It has long been known that this was the intention, but the news that all formalities have been successfully completed, and that operations in a large way are without question about to start, has been generally welcomed.

**Geologists Ready For Field Work.**—Dr. W. E. Cockfield and Dr. C. C. Cairnes, of the Geological Survey of Canada, have arrived in Vancouver. For eight seasons Dr. Cockfield has conducted geological survey parties to the Canadian Yukon Territory and now is on his ninth trip. He will work in the southern Yukon but intends, incidentally, to visit the Mayo District for the purpose of noting the development of the past two years. One-third of the Yukon, Dr. Cockfield says, has been explored and found rich in minerals, and the geological exploration of the remaining two-thirds is expected to be interesting in its results. Dr. Cairnes is to continue his work of last year in the district between Hope and Princeton in the Nicola-Princeton District of British Columbia.

Harlan I. Smith, archaeologist for the Canadian Geological Survey, also is in the Province prepared to carry on his field work. He will spend some time this summer among the Indians adjacent to Bella Coola, on the west coast of the provincial mainland.

Dr. G. S. Hume, of the Geological Survey of Canada, has passed through Edmonton, Alberta. He proposes surveying the region between Fort Wrigley and Fort Norman on the west side of the Mackenzie River. It is his intention first, however, to examine clays of reported economic value occurring between the Muskeg and Moose rivers and on the Calumet river. W. A. Kelly and J. O. G. Sanderson, Alberta University men, will conduct surveys on the Dahadinni, Red Stone and Little Bear Rivers.

Dr. M. Y. Williams will be engaged in geological survey work in southern Alberta this season.

**Chief Inspector Resigns.**—James McGregor, who has been Chief Inspector of Mines for British Columbia since the 10th of May 1920, has resigned the position because of ill health. The duties of the office will be taken over on the 1st June next by George Wilkinson, who was Chief Inspector from the year 1917 to 1920 and resigned to become General Superintendent of the Pacific Coast Coal Mines Ltd.

In making this announcement Hon. Wm. Sloan, Minister of Mines, stated that it was a matter of sincere

regret, not only to himself but to all officials of the Department of Mines, that Mr. McGregor should be compelled to relinquish office on account of poor health. He had been in the service of the department for about twenty-five years and had a record throughout that period of efficiency and conscientious attention to duty. From the age of fourteen years up to the date of his entry to the Civil Service he had been prominently connected with the coal mining industry of Vancouver Island. It was Mr. Sloan's hope, and that of all Mr. McGregor's associates, that he would be restored to complete health.

Mr. Wilkinson, who takes over the office, has had many years experience as a mine operator and engineer in this Province. Prior to becoming Chief Inspector in 1917 he was manager of the Western Fuel Company's Reserve Mine at Nanaimo. Born in Cumberland, England, May 27, 1875, he was at work in the mines there for five years before coming to Vancouver Island in 1896, since which time he has been engaged, practically without cessation, in and around the coal and metaliferous mines. His technical qualifications are the highest, as he holds a first-class manager's certificate for both British Columbia and Alberta and is a member of the B. C. Institute of Engineers.

**Trail Ore Receipts.**—Ore receipts at the Trail smelter, Consolidated Mining & Smelting Co. of Canada, for the week ending May 14th totalled 9,918 tons. The detailed shipments follow:

| Mine                     | Tonnage |
|--------------------------|---------|
| Alamo, Alamo             | 93      |
| Bell, Beaverdell         | 47      |
| Black Rock, Northport    | 40      |
| Company Mines            | 9,009   |
| Galena Farm, Silvertown  | 52      |
| Knob Hill, Republic, Wn. | 52      |
| Lone Pine Republic, Wn.  | 275     |
| Octagon, Okanagan        | 1       |
| Quilp, Republic, Wn.     | 286     |
| Sally, Beaverdell        | 33      |
| Silversmith, Sandon      | 125     |
| Standard, Silvertown     | 172     |
| Surprise, Republic, Wn.  | 51      |
|                          | 9,918   |

### GERMAN POTASH INDUSTRY IN 1922

The 1913 German pre-war record of an output of 1,110,500 metric tons of pure potash was surpassed in 1922 by about 200,000 metric tons; that is to say, the production was about 1,311,500. In judging these statistics the output of Alsatian potash -- no longer German -- must be considered. Statistics for the years 1913 to 1921 show the following development:

| Year | Total output of pure potash Metric tons | Total value Paper marks | Average value per ton Paper marks |
|------|-----------------------------------------|-------------------------|-----------------------------------|
| 1913 | 1,110,500                               | 185,466,000             | 167                               |
| 1914 | 903,900                                 | 150,603,000             | 167                               |
| 1915 | 679,700                                 | 102,011,000             | 150                               |
| 1916 | 883,900                                 | 157,369,000             | 178                               |
| 1917 | 1,004,200                               | 218,460,000             | 217                               |
| 1918 | 1,001,600                               | 278,677,000             | 278                               |
| 1919 | 812,000                                 | 1,260,301,000           | 1,552                             |
| 1920 | 923,600                                 | 1,517,865,000           | 1,626                             |
| 1921 | 921,146                                 | 2,072,101,000           | 2,250                             |

At the beginning of 1923 the price of potash to German consumers, measured in paper marks, was about 800 times that of pre-war times.

The world's consumption of pure potash increased from 1,100,000 metric tons in 1913 to about 1,600,000 metric tons in 1922. Of the latter amount, 1,300,000 metric tons were of German origin.—U. S. Commerce Reports.

Bauxite of the finest quality has been found in the Inverell and Tingha districts of New South Wales, Australia. The quantity in which it is available is now being investigated.

**CANADIAN MINING ENGINEER**, holding responsible position in United States, desires opening in Canada. Thoroughly familiar with all details of mine development and successful record in mine operation. Must give present employers reasonable notice. Reply; Box 583, Canadian Mining Journal, Gardenvale, Que.

### PURCHASE OF GOLD ORES

The attention of prospectors and others is drawn to the provision in the Mining Act of Ontario authorizing the Department of Mines to purchase parcels of gold ore taken out by prospectors and others in developing or working mining claims. Arrangements have been made by which such parcels of gold ore, whether large or small, will be accepted by the Temiskaming Testing Laboratories at Cobalt, and paid for according to the schedule provided for the purpose. The Laboratories are operated under the auspices of the Department of Mines.

This offers a first class opportunity for testing the value of ores on a large scale, and also of turning ore of good quality into money for carrying on further development work. By special arrangements, on less than carload lots, freight rates on the T. & N. O. Railway are reduced 50 per cent.

The Laboratories are also equipped for working out the best methods of treatment for gold or silver ores of a refractory or unusual character.

Full information as to treatment charges, schedule of payments, etc., can be obtained from the undersigned, or from A. A. Cole, Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

THOS. W. GIBSON,  
Deputy Minister of Mines

Toronto, 12th March, 1923

## Hercules Pine Oil Saves You Money

Experienced flotation operators are finding pine oil the most economical reagent they can use. It is the best frother known and recovers more concentrate than any other. It is the cheapest flotation oil when compared with others on the basis of the net cost per ton of ore treated.

Hercules Pine Oils are steam-distilled and consequently superior to oils distilled by other methods. They are produced under strict chemical control and are made to conform rigidly to specifications that will meet your requirements. A comparison of samples will prove their superiority.

Write for booklet No. 200 which gives specifications for our standard grades.

## What Angle Compound Compressors Will Do For You:

1. Provide a constant, reliable air power supply.
2. Cut in half the floor space devoted to Compressors.
3. Cut in half your foundation and installation charges.
4. Permit ready adaptation to any form or arrangement of power drive.
5. Lower your horsepower per 100 feet of air compressed.
6. Operate efficiently at partial loads.
7. In the "twin" direct motor driven units, avoid excessive peaks in the power inflow.
8. Require minimum attendance and repair.

Ask for an "Angle Compound" proposal  
on your new compressor

# Ontario's

# Minerals

PROVINCE OF ONTARIO

DEPARTMENT OF MINES

Hon. H. MILLS, Minister of Mines

## Mineral Areas.

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favorable for the occurrence of minerals, 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver mines of Cobalt occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

## Economic Minerals.

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario:—actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluor-spar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, Portland cement, brick and tile, meet every demand.

## Mineral Production.

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1921 to be worth \$48,128,387, of which the metallic production was \$27,574,202.

The following figures show the rapid growth of Ontario's mineral industry by five-year periods since 1891:

| Year. | Value.      | Year. | Value.       |
|-------|-------------|-------|--------------|
| 1891  | \$4,705,672 | 1906  | \$22,388,383 |
| 1896  | 5,235,003   | 1911  | 41,976,797   |
| 1901  | 11,831,086  | 1916  | 65,303,822   |

## Dividends.

Dividends and bonuses paid to the end of 1921 amounted to \$23,140,734 for gold mining companies, and \$84,388,185 for silver mining companies or a total of \$107,528,919.

## Mining Regulations.

A miner's license costs \$5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of \$2.50 or \$3.00 per acre, depending on location in unsurveyed or surveyed territory.

## Assay Office.

The Provincial Assay Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

## Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

## Assisting in the Development of the Mining Industry

It is essential that the peculiar banking needs of those engaged in the exploitation of Canada's natural resources be met with special facilities.

The Imperial Bank, ever a constructive element in the progress of Canada, long since realized the need for interested financial service to enable

the proper development of the mining industry.

By opening branches throughout the mining districts and continually adding to them, as necessitated by expansion, this Bank has materially assisted in the development of the industry throughout Canada.

Those whose business is mining will find our facilities adequate and our knowledge of conditions valuable.

# IMPERIAL BANK OF CANADA

Peleg Howland, President.

A. E. Phipps, General Manager.

## THE BUSINESS OF HOLMAN BROS, LTD. CAMBORNE, ENGLAND

is the specialised manufacture of Rock Drills, Compressors and Mine Hoists and the manufacture generally of Mine and Quarry requirements.

This business is carried on in three works employing upwards of 3,000 men, comprising laboratory, foundries and machine shops. The materials which are used are purchased only on analysis by our own metallurgist and not bought on a stereotyped specification. The finished products are all subject to working tests before shipment. We are therefore confident that the machines which reach our customers are sound physically and mechanically. This is proved by the large and growing list of customers using Holman products all over the world.

### REBUKE AND REWARD

If those of our readers who have preserved files of the *Canadian Mining Journal* will turn back to the issue of January 19th, 1923, page 56, they will see there a letter from Mr. Robert Holding. In this communication Mr. Holding administers a severe rebuke to a group of promoters who had been taking unwarranted liberties with his name. His letter is worthy of quotation *in extenso*. Here it is: — "My notice has been attracted lately to your articles on wild-catting, and the unscrupulous way in which mining companies are being organized for the sole purpose of milking the public. I have had more than my share of experience with one of these to which your article might have been meant to apply, and this might lead some people to believe that I am one of the principals in the undertaking alluded to.

"I refer to a newly organized company, under the name of 'Holding Consolidated Company, Limited'. I would like to clear myself of any unjust imputations by stating a few facts.

"I was the discoverer of the Holding mining claims in the West Shining Tree district and still hold 75 per cent interest in them. These claims were optioned to others, and I have had no hand in the incorporation of the company alluded to. I have endeavoured by every means possible to prevent any manipulation by which any person could be deceived.

"My claims were, and still are, under the incorporated name, Asquith Gold Mining Co. I had no knowledge of the Company mentioned above until I saw it in print."

An admirably outspoken and concise declaration, this.

And now comes the dramatic denouement. Evidently the promoters failed to put their scheme "across." A few days ago it was announced that Mr. Holding had disposed of his claims to Mr. R. J. Fleming (the well-beloved and heartily-hated former Traction Tsar of Toronto) for a good round sum. It transpires, also, that Mr. Holding, a vigorous octogenarian, seafarer and prospector, has sought his fortune in many far countries, and after numberless adventures by land and sea, has realized his dream of a modest competence. For once the gods have shown a sense of proportion.

The striking contrast between the plucky old gentleman (to whom we take off our last year's straw — perfectly cleaned) and those men who organize companies "for the sole purpose of milking the public", is a sermon that needs no rhetorical garnishings.

We extend to Mr. Holding the *Journal's* heartiest

hope that he will live long in the land that he has made his home. We also venture the further hope that Mr. R. J. Fleming may find mining a less costly avocation than amateur farming.

O, that Horace had done precisely what Mr. Fleming is doing!

### NEW BRUNSWICK COAL FOR QUEBEC AND ONTARIO

A Canadian coal district of modest productive capacity but with a favourable location for economic development is the Grand Lake area of New Brunswick, particularly in the vicinity of Minto, 70 miles north of St. John and 35 miles east of Fredericton. Until recently, when the Canadian Pacific Railway acquired holdings in the district, attempts to operate mines within this area were sporadic and on a small scale. Mr. Charles J. Coll is now in charge of the mining operations of the Minto Coal Company, and the output of the mines is increasing rapidly. The latest report of the Dominion Bureau of Statistics, giving coal production for February of this year, credits New Brunswick with an output of 25,000 tons, double that of a year ago, and most of this increase can be credited to the new activities round about Minto.

In evidence given last month before the Senate Committee on Fuel in Ottawa, Mr. W. B. Lanigan, General Freight Traffic Manager for the Canadian Pacific Railway, gave some facts about these coal mining operations. He said, in part: "We have a coal field at Minto, New Brunswick, and I may say that I have been trying to extend the market for that coal to the best of my ability. There is a big difference in hauling coal or any other commodity in the direction of your loaded traffic and filling empty cars to come back. We have a great many cars that go down to St. John in the winter time with grain, and if we can get something to put in those cars to bring them back with a load rather than empty, it is a more desirable and cheaper form of transportation than it would be to carry it in the opposite direction, the direction of your loaded cars.

"The Minto field is 841 miles from Toronto, and we made a rate of \$4.50 into Toronto for that coal. I don't think we carried any coal to Toronto, but we did increase the amount of coal we put into Montreal, into Ottawa, along the North Shore, and as far west as Kingston. I expect these Parliament buildings are heated with Minto coal. The rate to Montreal, a distance of 501 miles, is \$2.75, a little over half a cent per ton per mile, by using the return cars, available at St. John within a comparatively few miles of Minto."

The information available in the reports of the Geological Survey and other reports is summarized by Mr. F. W. Gray in his description of "The Coal-Fields and Coal Industry of Eastern Canada," published by the Mines Branch in 1911. Though thousands of square miles in New Brunswick are underlain by coal measures of Carboniferous age, containing in places thin seams of coal, the only promising part is that at Grand Lake, occupying an area of 112 square miles with an estimated content of 138 million tons.

The coal seam is thin, from 18 to 30 inches, and lies within fifty feet of the surface. The quality is good. A unique method of mining is employed to cope with these peculiar conditions. Shafts are sunk to work an area 800 feet by 600 feet and last about 18 months, when the equipment is moved on to a new block.

Though from the nature of the coal seams production from the Grand Lake field will never be very large, still, it constitutes a valuable local industry and, while helping the Canadian Pacific Railway to fill its empty west-bound freight cars, also aids in the solution of Canada's fuel problem.

### FIRST QUARTER'S PRODUCTION IN ONTARIO

The report of Ontario's mineral output for the first quarter of 1923 shows, in the main, a healthy condition in the youthful mining industry. The cramping effect of power shortage in Poreupine has cost the country numerous millions or dollars in delayed production of bullion; but private enterprise has at last overcome the forces of obstruction and the inertia of public administration, and when Hollinger has expended its three millions or so on the Abitibi River, many of the smaller mines will be able to add their quota to the enlarged production of the "big three".

The full effect of development in South Lorrain has not yet been felt in silver production, which is somewhat below that of 1922. With the Violet property of La Rose again producing and the new Colonial workings in good ore, the Cobalt camp should make a much better showing during the remainder of the year.

The outstanding feature of the year's progress so far is, of course, the recovery of the market for nickel. Though a large part of the renewed activity at the mines and smelters of the Sudbury district and at the refineries is due to the increase in general industrial activity, the initiative of the various managements in finding a wider market and in improving and adapting their products for multitudinous industrial uses must be credited with a substantial share of the success.

Lead now has an important place in Ontario's output of metals. This is due solely to the well-directed activities of the Kingdon Mining, Smelting and Manufacturing Company. The development of the mine at Galetta from the prospect stage and of the concentrator and smelter from their simple beginning to their present highly organized form afford an example of clean-cut and effective engineering and business management that

might well be used as a criterion by Canadian mining engineers. Those concerned in this development have earned the reward indicated in the official figures of production and value.

Iron ore is still conspicuous by its absence from the tables of production. Nor is any relief in sight from this intolerable situation. After the pending provincial elections are over, we may have some light thrown on the subject by the committee on iron ore appointed last July to examine all the evidence available. The business of smelting American iron ore in Ontario has been resumed on a very satisfactory scale; but that only emphasizes the opportunity that awaits us for using our own raw material.

### THE AIR FORCE AND AERIAL SURVEYS

The season's programme for the Royal Canadian Air Force has been announced. In addition to flights for the purpose of training, there will be a large number of flying hours allotted to various branches of the Government service. The Forestry, Water Power and Topographical Surveys and the National Parks Branches of the Department of the Interior, as well as the Departments of Public Works, Agriculture, Customs and Indian Affairs, will profit by this service. Photographic surveys will be made, survey parties and their supplies transported, fire patrols conducted. Altogether, this branch of the National Defence force will be put to a very valuable use throughout the summer months.

There is a gap in the list. Where does the mining industry come in? The mining industry must be the pioneer throughout the larger part of Canada and the mainstay of important areas. Its growth depends essentially upon exploration, much of it in areas that are still unmapped, or mapped with various degrees of vagueness and inaccuracy. Topographical maps of these areas would be of incalculable benefit to the prospectors and geologists who must toil through the woods on foot. An aerial survey is the cheapest and most satisfactory means of providing such a map.

Could not a small fraction of the flying hours available for the use of the various Government departments be used to aid the geologist and the prospector?

### WATER POWER

Canada's hydro-electric stations can supply 3,000,000 horsepower. The Water Power Branch estimates that by 1940, this figure will have reached 5,000,000. Mr. Julian C. Smith estimates that 20 or 25 years from now we shall have 7,000,000 horsepower developed. The coal equivalent of our present developed power is 26,700,000 tons a year, worth, at \$10. a ton, \$267,000,000. These and a wide range of additional facts and figures regarding our water-powers and their uses are cited in a noteworthy special number of the *Financial Times*, Montreal, issued last week.

The mineral industry consumes, directly, only a comparatively small part of this vast amount of hydro-

electric power. The energy, both human and mechanical, expended in the production of minerals is usually repaid on a far more generous scale than in other industries. In the metallurgical and allied industries dependent upon minerals for their raw material there is, however, an open field for the use of electrical power whose possibilities are vast, but impossible to gauge. A number of important electro-metallurgical industries already in operation will come to mind. These are merely on the borders of the field.

Canadian metallurgists have hardly got into their stride yet. The remarkably fine results they have attained in the comparatively few instances where they have applied themselves seriously impress one with the idea that when their numbers are increased and their scope enlarged, Canada will be known for the thorough quality and large size of her metallurgical industry. In this our hydro-electric power will play no small part. It is quite possible that, with the advance of metallurgical research, the minerals from many deposits, some already available and others still to be found, that are now of little or no use will be transformed to commercial commodities in somewhat the same way that limestone is now made into acetic acid at Shawinigan Falls.

### RESEARCH IN EVERY-DAY LIFE

"In an inland city two years ago, two bakers divided the bread trade between them on about equal terms. One was a college man, trained in chemistry and physics, who had gained an interest in a bakery through an unexpected inheritance. The other was a rule-of-thumb baker, who delighted in following the customs and instincts that had grown up slowly since the days of Noah and the ancient fathers of our race.

"To-day one of these bakers operates a plant that is a splendid exemplification of the work of the research chemist in the baking industry, while the other is blue and disconsolate. The bread in the plant of the man who believed in the chemist, rolls through automatic machines, nearly all of which were invented in response to needs discovered by chemical research. No hand touches it from mixer to wrapping machine. It passes through a 'foolproof' oven, in which a loaf simply cannot get out until it is properly baked, and the ingredients are subjected daily to chemical tests under a trained supervisor.

"It is the belief of the owner of this bakery that within ten years every baking superintendent will be a college man, with a technical training in the chemistry of fermentation. In his own plant the heart of the bakery is the chemist's laboratory, where ingredients are tested, weighed, and introduced into the bread mix with an exactitude of measurement never before thought to be necessary.

"To the chemist of this plant the housewife's 'pinch of salt' and the rule-of-thumb baker's 'small handful' become an abomination. Careful research, verified by the baking of thousands of loaves of bread in an exper-

imental bakery, has shown that just a pinch too much of salt or just a pinch too little will have a very marked effect in pulling down the quality of the baked loaf.

"In this bakery, too, a time clock has been installed. It is not a time clock for the purpose made famous by efficiency engineers in factories. It is a time clock in the dough room. It forces the baker to record the exact minute and second at which he took batches of dough from the mixers and the exact minute and second at which he 'punched' the doughs after the first fermentation in the troughs.

"This most recent work of the research chemists in stating the need for one new automatic machine after another to replace guess work and variable human judgment, oddly enough, is only a following along of the 'Open Sesame' to the secrets of fermentation discovered by Louis Pasteur."

These paragraphs commence a story, "The Earning Power of Research," in the current issue of *Industrial and Engineering Chemistry*. Many similar stories could be told, all pointing to the same conclusion, namely, that it pays — pays in cold hard cash — to know exactly what you want to do and precisely the most effective way of doing it, in any manufacturing process. Such a seeking and finding of information constitutes industrial research.

The term "research" still suggests a vague and distant ideal to many of us. The fact is that industrial research is mainly composed of applied common-sense, impelled to action by the same curiosity that "wants to see the wheels go round," and backed by a thorough training in the fundamentals of pure and applied science.

There are still many phases of both mining and metallurgy that have not yet profited by the use of organized scientific curiosity in the hands of a competent man. Many old methods are still retained in mine and smelter because of the reverence due their antiquity. The newer parts of our mineral industry have in the main escaped the results of this misplaced veneration; but hoary custom still rules in places.

The chemist-baker tells a story that all of us can note with profit.

In panning vein-matter for gold, the mortar and pestle are indispensable, as the sample must be well ground up before being panned, and every grain must go into the pan. As the gold in some deposits is so locked up in pyrite and other minerals that it does not separate in a pan, a sample should be first roasted (this can be done on a shovel) and ground before being panned. The sand and gravel of rivers that have crossed gold fields may pan gold, and, in this way, give an indication for prospecting up-stream.

Platinum is found associated with chromite in serpentine and peridotite rocks. Some large masses of platinum have been found, for example, one weighing 23 lbs. It is worth about five times as much as gold. It should be looked for in serpentine wherever the rock is mineralized, and particularly where chromite is found.

# LETTERS FROM SOUTH LORRAIN

## III. PROSPECTS AND PERSPECTIVE.

South Lorrain, because it is a resurrected camp, is in a position markedly different from that of a new mining camp. During the summer months steamboat service is available on Lake Temiskaming, the landing being four miles from Silver Centre by road. The road to North Cobalt and Haileybury is passable in dry weather. Thus Silver Centre, the heart of South Lorrain's small population, is easily accessible. The output of silver will—at a guess—exceed 3,300,000 ounces this year. Before long the re-vitalized district will be producing more silver annually than the mines of Cobalt. This seems certain. Meanwhile, as the summer goes on, men, machinery, and supplies will be needed in increasing volume. It is safe enough to predict that the population of South Lorrain, which is now about 300, will run up to one or two thousand before winter sets in. This means trade for the merchants of the nearest railway towns, traffic for the railway, and very timely replenishment of the diminishing annual supplies of silver and cobalt from Northern Ontario. In course of time, railway connection may be desirable. But, let me repeat, there is now the most glaring need of a macadamized wagon road. The outlay would be as bread cast upon the waters. The Government would gain an hundred-fold in revenue from the mines and from numerous other sources. All the good land between Cobalt and Silver Centre would be worked. Farming, stimulated by the new mining activities, is even now being carried on to a considerable extent along the lands served by the miserable Cobalt-Lorrain road; but it is not within measurable distance of its maximum.

One would have to be blind not to see the great possibilities of South Lorrain—and unvarnished not to admit seeing them. But it is not a region that invites surface prospecting. Heavy overburdens of boulder clay, sand, and gravel fill the depressions of the glacialized Archean hills. The valleys are either bedded with clay or occupied by lakes. Therefore most of the exploratory work that is being done is taking the form of diamond drilling (chiefly for formation) and shaft sinking, all of which involves the well-directed expenditure of much money. It is more than probable, therefore, that the future of the district lies in the hands of established mining companies to a large extent, and, to a lesser degree, in those of new companies that are amply financed.

Putting it briefly, South Lorrain will be developed by the geologist, the mining engineer, and the financier. The prospector has already done his bit. The stabilizing influence of the two operating companies, the precedents of sound methods set by them, are proving invaluable.

To paraphrase the good old lines, South Lorrain is a district.—

"Where many a prospect pleases

"And only man is vile."

Never in Canada has there been less excuse for hydrous promotions. The bare facts are abundantly good enough. Moreover, the seeker after sound advice can get it more readily than ever before. Much light is being thrown

upon the ore deposits, their character and their vagaries, by Mr. C. W. Knight's present investigations. The map compiled by Mr. A. G. Burrows and his assistants in the year 1910 is an excellent general guide. To ascertain the standing of any mining undertaking in this region, to get a humanly fair idea of the possibilities and probabilities of success, is an easy matter for the well-informed investor. The "average" small investor, however, has no idea how to go about getting this information. It would greatly assist all investors and it would strengthen the hands of legitimate promoters and operators, if the Ontario Department of Mines issued interim reports. It would be still better if the Department gave definite and definitive statements through the press, relating to economic possibilities and progress, and embodying warnings, tacit or outspokenly specific, against the flimflammer. In the circumstances this is a first duty of the Department. The public will listen. Any such rational preventives are infinitely more effective than "Blue Sky" laws. The latter can never take the place of timely publicity.

\* \* \*

The area of probable enrichment in South Lorrain may be larger in acreage than the corresponding area in Cobalt. This gives one pause. The younger camp is getting away to a better start. There should be fewer blunders made and fewer blanks drawn in South Lorrain than in Cobalt. The essential geological likeness of the two areas makes South Lorrain the heir to all the practical wisdom gained in the older camp.

The kinship between the ore deposits of Cobalt and South Lorrain is that of the closest family relationship. The general mineral association is the same. As has been indicated above, the vein enrichments occur close to, but not actually at, the contacts. This is especially the case when branching veins become consolidated into one main vein. There are, however, one or two observable differences. These may be summed up as follows:—

1.—Whilst the principal known ore-shoots in South Lorrain occupy fractures in which pronounced faulting has taken place, the pronounced faults at Cobalt are almost always devoid of ore-shoots.

2.—In South Lorrain, more especially in the Keeley workings, there is marked, deep-seated oxidation, reaching depths of at least 500 feet, beneath and surrounding which there are found secondary ores of silver obviously derived from the leached material above.

\* \* \*

A few words of appreciation are due the managements of the Keeley and the Frontier. At both mines there is the closest watch kept on daily and, for that matter, hourly, results. There is no evidence of the wastefully disproportionate overhead charges that often are the curse of successful mines. Mine maps, assay plans, and daily records are kept up-to-date. Supervision and direction are as they should be—efficient and unobtrusive. Mining geology is a recognized factor in daily progress. Accommodation for the men is good, the commissary departments are more than good.

Ville Marie, Province of Quebec, is not close enough to

# Progress of Continental Mines

SILVER ORE ON COLONIAL PROPERTY, AND  
PLANS TO OPEN UP KIRKLAND AREA

BY THE EDITOR

The events of the past few weeks at the Colonial property of Continental Mines have been the most momentous in the Cobalt camp for years past. The new shaft, sunk to the diabase-Keewatin contact, a distance of 950 feet, since this company took over the property a year ago, has opened up ore that is not only wonder-

that now supplies the world with the larger part of its gold.

The Colonial and Violet properties adjoin the O'Brien Mine on the east. To the east again of the Colonial is the Silver Cliff, also held by Continental Mines. On the O'Brien property there outcrops the contact, with the underlying Keewatin rock, of the diabase sill whose intrusion induced the forming of all the Cobalt silver veins. It is at or near the contacts, upper and lower, of this sill with the intruded rocks that the silver deposits are found. On the O'Brien property exceedingly rich veins were found outcropping along this lower contact zone, and they have continued far underground, dipping eastward with the contact. On the Silver Cliff property to the east there is a small remnant of the Keewatin rock that originally covered the diabase sill at this place, and in it and the adjoining diabase rock there were found numerous shallow silver veins, to treat the ore of which the Silver Cliff mill was built. On the King Edward property to the south a diamond-drill hole showed the lower contact to be at a depth of 1,150 feet. Apart from this drill hole and the mining development following downward from the outcrop, on the O'Brien and the Violet claim, the new Colonial shaft is the first serious attempt to explore this large area of the lower contact, which holds out such promise

New Colonial Shaft, looking southeast. The diabase-Keewatin upper contact occurs near the top of the hill in the background.

fully rich, but exceeds in its extent, so far, the most sanguine expectations. If further lateral exploration of this contact should show that this ore is of wide spread occurrence, as may reasonably be expected, the capacity for production of Canada's famous silver camp will be greatly increased.

It has required the courage born of conviction to spend well over \$150,000 for a shaft to open up this ground for exploration. This conviction was based on a thorough examination of all the facts available, and logical scientific deduction from these facts. A similar course of reasoning led some of the owners of outcrop mines on the Rand to sell their holdings, buy "deep" holdings, and sink shafts to the buried reef

affect the stability of the popular centre of gravity, nor is it hopelessly and aridly remote.

A generation hence, when history shall have been written, I fancy that South Lorrain will be described as having proved a brilliant successor to its brilliant predecessor, Cobalt.

J. C. MURRAY.

Vein at 935-foot level of Colonial shaft. The face shows ore to a width of 9 feet, giving assays averaging 20 to 100 ounces across that width, exclusive of the calcite vein in the centre which is composed of high-grade ore running several hundred ounces to the ton.

to the gold speculator. Indeed the published conclusions of Mr. C. W. Knight, of the Ontario Department of Mines, after his recent thorough geological study of the Cobalt camp, are so clear cut and decided that no one need hesitate in exploring in a comprehensive way the low content of the diabase sill, in favourable localities, can be sunk almost as an investment.

The accompanying photographs were taken a month ago. Since that time underground development has

Silver Cliff mill, on Cross Lake, east of the Colonial Mine.

proceeded steadily, and soon there will be sufficient ore developed to warrant the operation of the mill on the Silver Cliff property.

At Kirkland Lake the plan of operations of Continental Mines has been equally far-sighted and comprehensive. During the nine months of their ownership of the eastward extension of the "main break," they have conducted a thorough examination of some of the more promising localities and have sunk a shaft 150 feet on the northern of two shear zones or "lines of break." This shaft has disclosed some very interesting gold ore. As it was sunk by hand drilling and horse-power, it has not been possible to push development rapidly in order to explore the shoots of ore indicated in the

Temporary building, headframe, and horse-whim on Post Claim of Continental Mines, Kirkland Lake, on May 9th. South of this prospect shaft the new shaft will be sunk.

shaft. Now, however, arrangements have been made for an adequate supply of hydro-electric power, and progress in this shaft and in drifts from it will be rapid.

The southern shear zone, a thousand feet away, which is considered by some to be the "main break," has not yet been seriously examined within the Continental's holdings. It has been decided to commence immediately a 600-foot shaft on it, from which exploratory drifts will be run 1500 feet east and west along the "break" with a view to exploring thoroughly its possibilities. The western producing end of the Kirk-

land gold belt has yielded such handsome returns as a result of underground exploration of this sort, that the group of mining engineers who are backing and directing the Continental operations are confident they will develop a mine or two on their end of the belt by adopting similar means.

The mining fraternity in Canada will watch with interest the progress of Continental Mines in their ventures at Cobalt and at Kirkland Lake; and it may be that the results will open out a new vista for those who wish to direct the development of Canada's mineral resources in a sound and comprehensive way.

## PERSONAL AND GENERAL

Mr. W. R. Rogers is in Porcupine for the week, to see the detailed topographical mapping for Mr. A. G. Burrows' new map sheet well commenced.

Dr. R. B. Moore has resigned his position as chief chemist and mineral technologist with the United States Bureau of Mines to take charge of the development department of the Dorr Company at their New York office. Dr. Moore has had an unusually varied and successful experience with non-metallies and some of the rare metals, and was especially concerned during the war years with helium and radium recovery.

Mr. Dan Lindeborg, pioneer prospector and mine operator, has passed through Vancouver en route to Stewart after wintering at Honolulu. He is the owner of the Big Missouri claims, under bond to the Trites-Wood-Wilson syndicate.

Mr. J. J. McDougall, assistant general manager of the Acadia Coal Company, Stellarton, paid a flying visit to Cape Breton recently in connection with the business of his company.

Mr. John S. Whyte comes back to the Dominion Coal Company to fill the position of Chief Engineer, recently vacated by Mr. Karl H. Marsh. Mr. Whyte was formerly electrical and mechanical engineer and was transferred to the Acadia Coal Company, Stellarton. He has received a warm welcome to Glace Bay where he is well known. He has the advantage of knowing the plants he will now supervise.

Mr. Thos. Riggs, vice-president of the Continental Mines, has been visiting the company's properties in Cobalt and Kirkland, accompanied by Mr. Shonnard, of the firm of Shonnard & Company, New York brokers, who had charge of the issue of Continental stock.

Mr. H. S. Denny is at present in the gold district of Northern Ontario, in the interests of his London associates.

Dr. C. V. Corless sailed for England last week.

## LEASED GOLD AREAS IN SOUTH AFRICA

The Government of South Africa owns certain productive areas in the Rand. One of these, the New State Areas, was leased five years ago to a company of that name, which has spent £1,800,000 in developing the gold-bearing reef underlying the property and building a 600,000 tons a year mill, recently put into operation. The famous Modderfontein Government Areas mine is another leased property, and there are a number of others, from all of which the Government derives a handsome revenue. Recently a new area, the Geduld East, was offered for lease, but no tenders were received. It is said that, for an unproved area, however promising, the terms of lease are now too onerous and the conditions of tenure, owing to the possibility of a Nationalist-Labour government, too uncertain to attract capital. It is estimated that £1,850,000 would be required to prove and then to equip the property.

# Metalliferous Production of Ontario

## RETURNS FOR FIRST QUARTER OF 1923

Returns received by the Ontario Department of Mines from the metalliferous mines, smelters and refining works of the Province for the three months ending March 31st, 1923 are tabulated below. For purposes of comparison the quantities and values are given for the corresponding period in 1922. Tons throughout are net tons of 2,000 pounds.

### ONTARIO'S METALLIFEROUS PRODUCTION — FIRST QUARTER OF 1923

| Product                   |        | Quantity  |           | Value \$  |           |

\* Copper valued at 10¢ in matte form and nickel at 20¢ in 1923.

\*\*Total output of pig iron was 102,515 tons worth \$2,745,605. Figures in the table represent proportional product from Ontario ore smelted.

### Gold

Although Ontario's gold output for the first quarter of 1923 was exceeded by that of 1922, the reduction is entirely due to hydro-electric power shortage. The snowfall was light in the early winter, and all small feeders in the drainage basin were frozen solid. This situation followed by a late spring had the effect of greatly curtailing milling operations at Porcupine. Additional power from Sturgeon Falls on the Mattagami river and Indian Chute on the Montreal river, will provide additional energy. Details of production are given hereunder:

| Source                             | Milling Capacity<br>Tons<br>(Daily) | Ore Milled<br>Tons | Gold Recovery |           | Silver Recovery |          |
|------------------------------------|-------------------------------------|--------------------|---------------|-----------|-----------------|----------|
|                                    |                                     |                    | ounces        | Value \$  | ounces          | Value \$ |

| GRAND TOTAL                        | 7,470                               | 464,939            | 213,263       | 4,373,513 | 33,321          | 21,885   |

In addition to the values above quoted, gold mining companies received a premium on exchange totalling \$15,745.

### Silver

Production for the quarter shows a small decrease from the 1922 figures, explained in part by the absence

of shipments from Gowganda by the two leading producers, Miller-Lake O'Brien and Castle-Trethewey. South Lorrain is producing at an increasing rate, the shipments from the Keeley and Frontier being 826,775 ounces of silver in addition to cobalt. The T. and N. O. Railway reports shipments of ore and concentrates as follows: to Ontario refineries, 523 tons and 247 tons to

the U. S. The average price of silver for the quarter was 65.845 cents per ounce as compared with 65.06 cents in 1922. Mines shipping over one-quarter million ounces follow in order; Nipissing 910,980 ounces, Keeley 530,174 ounces, Mining Corporation 310,697, Frontier 296,601, Coniagas 268,374. Mines report payment for 132,222 pounds of cobalt. Details of silver output are:

|                                 |                |                   |
|---------------------------------|----------------|-------------------|
| Cobalt, South Lorrain, etc. . . | 2,685,077 ozs. | Value \$1,763,522 |
| Recovered from gold refining    | 33,321 ozs.    | Value 21,885      |
| Recovered from Nickel-copper    | 11,351 ozs.    | Value 7,469       |

Total . . . . . 2,729,749 ozs. Value \$1,792,876

**Refineries:** South Ontario silver refineries at Deloro and Thorold treated 1773 tons of ore, concentrates and

residues during the quarter. Nickel-cobalt compounds include unseparated oxides and residues marketed. Production of nickel oxide and metallic nickel is insignificant as compared with the output from nickel-copper refineries. In addition to the items noted in the table, 660 tons of white arsenic worth \$154,069 were

marketed, the Deloro company operating a plant for the manufacture of insecticides.

#### **Nickel and Copper**

Production from the Sudbury area is on the increase following the post war depression. The Mond Company has a plant at Clearfield Pa., for the production of malleable nickel, and the International Company now operates at Huntington, W. Va., a rolling mill for nickel and monel metal products. The industrial uses of nickel are rapidly expanding. In April an announcement was made that mine, smelter and refinery of the British America Nickel Corporation would be soon placed in operation after a prolonged shut down. During the period the Mond and International companies smelted 192,118 tons of ore and produced 10,748 tons of nickel-copper matte. The Mond Company made no shipments, but the International shipped 2,271 tons of matte to Huntington, W. Va. and 6,234 tons to Port Colborne, Ont. At the latter plant 6,764 tons of matte were treated. The price of electrolytic copper on the New York market averaged 15.56 cents per pound for the period as compared with 12.96 cents in 1922.

#### **Iron Ore and Pig Iron**

The only iron ore shipped during the period was a consignment of 307 short tons of briquettes by Moose Mountain to Welland, Ontario. No Ontario ore was smelted in blast furnaces, consequently the Province is not credited with any pig iron production in the table. The Steel Company of Canada had a considerable tonnage of Moose Mountain briquettes on hand at the end of the quarter to be smelted later in connection with the experiments being conducted by the Ontario Iron Ore Committee.

During the quarter two blast furnaces at Sault Ste. Marie and two at Hamilton were operated. In the month of April another stack at Sault Ste Marie was blown in, also one at Port Colborne. Foreign ore totaling 194,091 short tons was smelted, the output of pig iron being 102,515 tons worth \$2,745,605. In steel making 62,241 tons of pig were used and 66,459 tons of scrap iron were used for the production of 115,967 tons of steel, valued at \$4,114,074.

#### **Lead**

The average New York price for pig lead was 7.98 cents per pound as compared with 4.71 cents for the corresponding quarter in 1922, and there was an increase in output as noted in the table. Early in the year the Kingdon Mining, Smelting and Manufacturing Company at Galetta on the Ottawa river placed in commission a new blast furnace for the treatment of slags and flue dust which had accumulated from Scotch hearth smelting of lead concentrates. The Company is now in a position to handle customs ore.

### **NO STRIKE IN NOVA SCOTIA**

The coal mines of Cape Breton, after conferences with officials of the Dominion Coal Company, have decided not to press their claim for a return of the 1921 wage rate. They will abide by their present contract, according to all indications. The steel workers have likewise decided not to strike for the 20 per cent increase in wages and the check-off they had demanded from the British Empire Steel Corporation. The recent voluntary increase of 10 percent in their wages no doubt affected their decision.

The output of the Dominion Coal Company's mines in Cape Breton during May was 310,000 tons, an increase of 103,000 tons over May, 1922. No. 2 Colliery had the largest individual output, with 61,000 tons.

### **ONTARIO DEPARTMENT OF MINES GEOLOGICAL FIELD PARTIES, 1923**

The geologists attached to the staff of the Ontario Department of Mines will be engaged in field work during the present season as follows:

#### **Permanent Officers**

(a) Mr. C. W. Knight, completing the geological examination of the underground geology of Cobalt and South Lorrain.

(b) Mr. A. G. Burrows, continuing his detailed mapping of the productive part of the Porcupine Gold Area. Some detailed topographical mapping is being undertaken at Porcupine by Mr. F. M. Smith, who is attached to Mr. Burrows' party.

(c) Mr. P. E. Hopkins is working in areas adjacent to Kirkland and Larder lakes. His map including the area between Swastika and Larder Lake will be issued during the present summer.

#### **Temporary Assistants**

1. Dr. Bruce Rose, lecturer in the Depts. of Geology and Mineralogy Queen's University, is assisting Mr. A. G. Burrows for a fortnight in June, and will later examine the area west of Lake Nipigon and south of the Canadian National (Transcontinental) Railway. He will accompany the survey party of Lang and Ross, of Sault Ste. Marie, who are running base and meridian lines in the District of Thunder Bay.

2. Dr. E. L. Bruce, Professor of Mineralogy at Queen's University, is in charge of a party making an examination of the Red Lake area in the District of Patricia. Dr. Bruce made a rapid survey of this area last season and a preliminary map will be issued in the near future. Before the conclusion of the season's work he will complete his survey of the English River, which was carried from Lac Seul to the mouth of Wabigoon river last season.

3. Mr. E. W. Todd of the Department of Mineralogy of the University of Toronto is in charge of a party examining the area northeast of Penhorwood township on the former Canadian Northern Railway. This area lies S. W. of Porcupine and west of the townships examined by Mr. Todd last season.

4. Mr. R. G. McConnell, former Deputy Minister of Mines at Ottawa, is completing his examination of the area adjacent to Sault Ste. Marie. Two seasons have already been spent on this work.

5. Mr. J. P. Johnson, a graduate of Toronto University, is attached to the survey party of Phillips and Benner, who are running a meridian in Thunder Bay District from Allanwater station on the Transcontinental Railway north to the easterly end of Lake St. Joseph. This party is also running a base line in the vicinity of Lake Savant.

### **CANADA'S MINERAL PRODUCTION**

The Dominion Bureau of Statistics has just issued its final report on the mineral production of Canada during 1921. It is, of course, much more comprehensive than the preliminary reports that have preceded it, and includes a vast amount of data, logically and conveniently arranged. The scope of the report in its present form is much wider than when it was published by the Department of Mines, and there is no doubt that the compilation in the first instance of the vast amount of information required for the tables that fill more than half the 233 pages accounts adequately for the unusual delay in publication. The volume is a credit to Mr. Cook and his staff on the Mining, Metallurgical and Chemical Branch.

# Northwest Mining Convention

SUCCESSFUL MEETINGS IN SPOKANE

No more convincing proof of the renewed health and life of the mining industry in the American Northwest could be obtained than is furnished by the outstanding success of the 28th Annual Northwest Mining Convention held at Spokane, Washington, from the 22nd to the 25 of May inclusive. Delegates were in attendance from the States of Oregon, Washington, Idaho and Montana and from the Province of British Columbia and the Yukon. General attendance aggregated, according to conservative estimates, at least 75,000 people, which indicates that in the City of Spokane and the adjacent district interest in mining is not confined to those directly identified with the business. In the past there have rarely been more than 75 properties represented in the exhibits; on this occasion there were 200 from British Columbia alone. Incidentally, the Canadian display captured the first prize.

## The Mineral Exhibits

Frank C. Bailey, the secretary, stated that there were some 10,000 specimens of ore in the exhibit, which was centrally located under the Milwaukee viaduct at Howard Street. The Coeur d'Alene mines were represented by large pieces of galena and other ores from the Bunker Hill, Hecla, Hercules, Morning, Tamarack & Custer, and Success mines, as well as from others. The Bunker Hill Smelter displayed bullion, and lead pipes from 3 to 12 inches in diameter among other products. The British Columbia Chamber of Mines showed samples from 200 properties in western British Columbia and the Yukon, while the eastern sections of the Province were well represented by exhibits assembled by the Associated Boards of Trade, the Prospectors' Associations, and other organizations, and taken to the Convention by Fred A. Starkey and associates, of Nelson and Cranbrook, B. C. In the centre of the hall was a very large piece of ore, labelled as containing 100 ounces of silver to the ton, taken from the Argentine Mine, Wallace, Idaho. A smaller sample from the same mine was said to carry 1,000 ounces silver to the ton.

Tuesday, the 22nd May, was Washington Day, and proceedings opened with F. A. Ross, vice-president of the Mining Association in the chair. A welcome was extended by Mayor Fleming, of Spokane, and by George Phillips, vice-president of the Spokane Chamber of Commerce. C. A. Towne, publicity director of the Anaconda Copper Co., told "What Mining Means to Montana", giving figures showing the influence of copper and its production by his Company on every citizen of the State of Montana. J. F. Callbreath, secretary of the American Mining Congress, in a discussion of transportation tariffs and taxation, urged that taxation should be based on the production of mines and not on their mineral content. Frank E. Woodside, of the B. C. Chamber of Mines, extended greetings from Canada. In the evening the delegates and visitors were entertained by moving pictures of the Anaconda Copper Company's operations.

## Technical Papers and Addresses

It was "Idaho Day" on the morning of the 23rd May and the programme consisted of addresses on "The

Silver Situation" by Dean F. A. Thomson, of the University of Idaho; "Recent Improvements in Flotation" by A. W. Fahrenwald, ore dressing engineer, U. S. Bureau of Mines; "The Metal Mining Outlook in Idaho" by Stewart Campbell, State Mine Inspector; and "Congressional Legislation" by Ravenel MacBeth, secretary Idaho Mining Association. Mr. Fahrenwald advised the engagement of a specialist in determining methods and equipment to be used, even if this meant an increase in costs. Mr. MacBeth stressed the difficulty of educating Congressmen to the needs of mining. Few mining men were appointed to congressional mining committees and the knowledge of the average congressman on the subject was extremely limited. The industry depended on Western senators to block injurious legislation. Ambassador Poindexter had been highly valuable to the industry while in the United Senate. L. O. Howard, dean of the mining faculty, Washington State College, said that mining had been handicapped by "blue sky" laws, taxation and railway freights. It had made important gains in the last year but lacked much of being in the position it occupied in 1914. He found conditions that encouraged him to believe it was entering on a long period of improvement.

"Oregon Day", to which was devoted the afternoon session, witnessed first-class addresses on mining conditions in that State. The contributors included Warren D. Smith, of the department of geology, University of Oregon, on "Mining Resources of the Baker District"; R. M. Betts, manager of the Cornucopia Mines Co. on "The Cornucopia District"; H. E. Hendricks, editor of the *Baker Herald*, on "Mines of the Baker District"; and J. P. Winter, of Portland Ore., on "Smelting Enterprises of Eastern Oregon."

## British Columbia

Thursday was the big day of the Convention. Affairs of the State of Montana were discussed in the forenoon, while British Columbia was in the limelight in the afternoon. Hon. Wm. Sloan, Minister of Mines, spoke for the Province, giving figures showing the progress made in 1922 in point of output as compared with previous years and sketching the developments of the past twelve-month. His tone was optimistic throughout and his prediction of increased output was enthusiastically received. A. G. Langley, resident mining engineer for the Government in the Kootenays, gave details of mining conditions in that part of British Columbia, and F. A. Starkey and other speakers from north of the line were heard and closely followed.

"Blue sky" legislation received another blow at the hands of Mr. Callbreath, who declared that it had an adverse effect on the development of natural resources. Other speakers included Douglas Lay, Manager of Le Roi No. 2, Rossland, B. C.; Frank E. Woodside, of Vancouver; Sidney Norman and Frank A. Ross, of Spokane.

A number of resolutions were adopted. One condemned the U. S. Treasury authorities for shifting 14,500,000 ounces of silver into subsidiary coinage. Another recommended the killing of the Denison "Blue sky" law before its introduction at the next Session. A

third suggested that the removal of the Alaskan land location office from Juneau to Anchorage remain in abeyance until conditions are investigated by President Harding on the occasion of his visit to that territory this summer.

### Prospecting

Friday, the 25th May, was devoted to miscellaneous business the greater part of the formal proceedings being concerned with the subject of "Prospecting." In this connection an informative address was delivered by R. W. Meldrum, of the Spokane University, while J. W. Mulholland, one of British Columbia's pioneer prospectors and mine operators, talked on what he described as "The World's Greatest Unexplored Free Milling Area." Mr. Meldrum stated that the prospector was the pioneer of all countries and he portrayed the work he had done in India, Australia, Africa, New Zealand and other countries. Mr. Mulholland declared, without qualification, that the "Greatest Unexplored Free Milling Area" was British Columbia and he gave many facts in substantiation of a statement which many might consider somewhat sweeping.

### Bolshevists Propaganda Exposed

Mr. Callbreath, secretary of the American Mining Congress, referred in strong terms to the activities of Bolshevists, parlor and organized, in the country. His remarks, he said, were inspired by the press dispatches, one of which told of the endorsement by a newspaper organization of a movement to "curb the usurpation of power by the United States Supreme Court" and the other of the plan of former U. S. Senator Frelinghuysen "to organize a league to limit the powers of coal companies and to force them to publish facts on the costs of production and distribution." Mr. Callbreath declared that "the attack on the Supreme Court is general among all parlor and organized Bolshevists. While some of them are patriotic, they do not realize what they are trying to do. Senator LaFollette, before the American Federation of Labor last year, said that Congress by re-enactment of a law might nullify the action of the Supreme Court by declaring it unconstitutional. If Congress is supreme in the making of law it might make law perpetuating its existence indefinitely. You have then created a monster autocracy, and if you assume that Congress is to be supreme and the full judge of its constitutional acts, then there is no Constitution. Instead of a Constitution you have a floating raft on a sea of shifting prejudices."

### ZINC SMELTER SOLD

It is reported that the National Smelter Works at Avonmouth, which were erected by the Government during the war at a cost of £3,000,000, but which were never utilized for the intended operations, have been sold to Baldwins Ltd. The buyer, it is understood, aims to realize the original plan of importing Australian ores or concentrates direct and of carrying out at Avonmouth—probably in conjunction with the existing Swansea concern—the processes of roasting or calcining required for their conversion into spelter.

### CYANAMIDE IN ITALY

Italy's production of calcium cyanamide rose from 16,000 tons in 1921 to 33,422 tons in 1922, and it is estimated that in 1923 it will be 40,000 tons. It is used principally as fertilizer. The fixation of atmospheric nitrogen by this means has distinct possibilities in Canada on account of the availability of cheap hydro-electric power.

### SLATE

"The Characteristics of Slate" is the title of a paper to be presented by Dr. Oliver Bowles at the meeting this month of the American Society for Testing Materials in Atlantic City. It gives a succinct account of the origin of slate, its valuable properties, its principal uses and suggested standards and tests.

Though slate has its origin in beds of clay, it has very little clay in it when it is of good quality. A typical slate contains the following minerals;

|                           |           |
|---------------------------|-----------|
| Mica (sericite) . . . . . | 38 to 40% |
| Chlorite . . . . .        | 6 to 18%  |
| Quartz . . . . .          | 31 to 45% |
| Hematite . . . . .        | 3 to 6%   |
| Rutile . . . . .          | 1 to 1½%  |

The crystals, most of them tabular, are arranged in a parallel position, and this gives rise to the slaty cleavage. It is of medium hardness, is very fine grained, is of low porosity, has great strength and is very resistant to weathering and many chemicals. The chief colours are grey, black, green, red, purple and mottled.

The uses of slate are manifold, and are increasing rapidly as its properties become better known. The principal uses are for roofing, electrical switchboards, blackboards, steps, toilet enclosures, etc. Only slate with a high degree of electrical resistance should be used for switchboards.

Slate splits most easily while the "quarry sap" is still in it. Sometimes it contains minerals soluble in water or weak acid solutions, which causes it to weather easily. The colour is sometimes fast, and sometimes alters on exposure to the weather, the former usually due to the presence of the stable oxides of iron, and the latter to the weathering of grains of carbonates or of pyrites.

Dr. Bowles suggests the following standards for slate:

**Roofing Slate.** — 3/16 inch minimum thickness is recommended. The adoption of a small number of standard sizes is not recommended, as a large number of sizes allows of the sheets of slate split from the blocks being used to the best advantage; much more trimming and loss of slate would result if there were fewer standard sizes. It is suggested that the present descriptions of colour, which are difficult for the user to understand, should be made plain to all. A three-inch lap is recommended as the standard for roofs. Durable nails should be specified.

**Structural Slate.** — For sanitary uses, the porosity should be specified. For strength and abrasion more investigation is needed before standards can be adopted.

**Blackboard Slate.** — It is estimated that only 10 percent of a quarry's product will make blackboards, and only 10 percent of these are flawless. Therefore a specification must take cognizance of this fact, lest a rigid standard make the price too high.

**Electrical Slate.** — "There is urgent need of the establishment of definite specifications and standard tests for electrical slate." It is stated that an apparatus suitable for conducting tests at the quarry is now available. Much experimented work remains to be done before a rational set of standards can be formulated.

# Power for The Mineral Industry

HYDRO-ELECTRIC GENERATING STATIONS IN  
NORTHERN ONTARIO GIVE 100,000 H. P.

(From *The Financial Times*)

The foundations of the mining industry of Northern Ontario consist of: large and rich mineral deposits; convenient location and transportation facilities; ample power for mining operations. The presence of these factors in Northern Ontario, together with a market for the products has given rise to its prosperous mineral industry. The central electric stations distributing power for mining purposes in Northern Ontario have a total installation of over 100,000 horse power and are here listed:

## Central Electrical Stations Distributing Power for Mining

| Company                          | H. P.  |
|----------------------------------|--------|
| Algoma Power Co. . . . .         | 1,600  |
| Algoma Steel Corp. . . . .       | 2,400  |
| International Nickel Co. . . . . | 21,300 |
| Lorne Power Co. . . . .          | 9,600  |
| Wanapitei Power Co. . . . .      | 9,966  |
| Nor. Ontario L. & P. Co. . . . . | 20,420 |
| Gowganda Power Co. . . . .       | 800    |
| South Bay Power Co. . . . .      | 250    |
| Great Northern Power Co. . . . . | 6,000  |
| Associated Gold Fields . . . . . | 1,600  |
| North. Canada Power Co. . . . .  | 19,800 |
| Lower Sturgeon Power Co. . . . . | 8,000  |

Total H. P. . . . . 101,670

The Ontario output of metals had been of some importance for many years, but pre-eminence was not reached until the opening up of the newer sections of the province by the construction of railways led to phenomenal discoveries of mineral wealth.

## 8 Plants, 40,000 H.P. for Nickel

The first of these was the discovery in 1884 of the copper-nickel deposits near Sudbury, first mined for their copper content but later attaining tremendous importance for their nickel content; during the great war the demand for both nickel and copper was greatly stimulated and the peak of production was reached during this period, the value of the nickel mined in 1918, when refined, was \$37,000,000; the value of the copper mined in 1916 passed \$12,000,000. The commercial importance of nickel is a comparatively modern development and consequently the mining and refining of this metal has only recently become intensive. At the present time there are eight hydro-electric plants with a total capacity of 40,000 horse power developed primarily for the nickel industry, and their importance can be estimated when it is realized that previous to their construction the industry, as far as Ontario was concerned, was confined to the production of copper-nickel matte, which was exported to Wales and the United States for refining.

With the armistice the need for nickel lost its artificial stimulus and production had to be curtailed until the surplus stocks of this metal were absorbed. Present indications are, however, that this process is about complete and that the mining of nickel will shortly open

up a staple industry to supply the ordinary demands of peace.

## 20,000 H.P. in Silver Region

In 1903 the next great discovery — that of silver — was made and during the early years of the Cobalt mining consisted in the winning and export to refineries of vast quantities of rich silver ores. The effect of this discovery made itself felt in 1905, when the silver output passed the million dollar mark, steadily increasing, reached a peak value of nearly \$18,000,000 in 1912. As the supply of high-grade ore declined, the practice of milling low-grade ores improved and the silver industry is now consolidated into the hands of three or four large corporations which maintain a steady output of some ten million ounces annually.

The influence of water power development in making possible this consolidation and stabilization of the silver industry, existing as it does in a country where coal is very costly, may be gauged by the fact that the first development was not installed until 1910 and that now upwards of 20,000 horse power is employed in the silver regions of Cobalt and Gowganda.

## 20,000 H. P. for Gold

The discovery of gold at Porcupine in 1909 was made by prospectors seeking new silver fields. The gold industry, however, did not lend itself to any preliminary individualistic mining such as characterized the silver finds. The first requirement for successful operation was a supply of power, and consequently no increased output of gold occurred until the Northern Canada Power Company had developed power at Sandy Falls and Wawaitin Falls on the Mattagami river — 2,400 h. p. was installed at the former site in 1911 and 6,900 h. p. at the latter in 1912. The effect of this was remarkable, and the output of Ontario gold in 1912 was 100,000 ounces greater in 1911 and has grown steadily until the annual output is approximately 1,000,000 ounces. This increase in production has been made possible by the increase of power development, which is now approximately 20,000 h. p.

## More Power Being Developed

The mining industry of Northern Ontario can now be said to have reached a point where a long and stable production of gold, silver, nickel and copper can be anticipated. The reserves of ore in sight in each case are very great, and new finds, a percentage of which should prove important, are constantly being reported.

Official records show clearly that all the power that can be required is readily available, and it is interesting to note, as indicating the faith of mining corporations in the future of the industry, that not only has a lease been secured from the Quebec authorities for an important power site on the Quinze river, presumably for gold mining purposes in the Porcupine region and the new gold district in Quebec, but also the Hollinger mining interests are reported to have secured a lease for the "Carrying Place" site on the Abitibi river where, it is stated, 20,000 horse power is shortly to be developed.

## THE FIRE RESISTIVE PROPERTIES OF GYPSUM

Gypsum has taken its place among structural materials in such products as plastering sand, wall board, plaster board, partition and flooring tile, Keene's cement, and gypsum blocks for the protection of columns. In Appendix III of the Report of Committee C-II of the American Society for Testing Materials, to be presented at the forthcoming meeting in Atlantic City on June 24-29, Mr. S. U. Ingberg discusses the fire-resisting properties of gypsum and gypsum products.

Gypsum products are made of gypsum with varying amounts of water to which may be added various fillers such as sand, cinder, wood fiber, or metal. When gypsum or any of these products are heated, the mixed water is first evaporated, after which the combined water of the gypsum is driven off. If the temperature is moderate (107 deg. Centigrade) the loss of water may stop at three-fourths of the total combined water of the gypsum, leaving the product as plaster of Paris with the impurities of the gypsum and the filler, if any. In practice, this change takes place over a wide range of temperature, being influenced by the conditions and the substances present other than gypsum.

When gypsum products are exposed to fire the temperature-rise is retarded not only by the poor heat conductivity of the material, but by the evaporation of the mixed water and by the consumption of heat in dehydrating the gypsum. But since anhydrite, the product formed by complete dehydration of gypsum, is specifically heavier than gypsum, the change caused by heat is accomplished by shrinkage and cracking. In this way the heat-insulating power is impaired. This effect is reduced by the addition of an incombustible filler.

Tests have shown that steel columns and reinforced concrete columns protected by gypsum or gypsum products stand exposure to fire for considerable periods without collapsing under pressure. For example, columns so protected with gypsum materials 2 inches thick, applied as molds re-inforced with wire, have withstood a 4-hour fire exposure "with an indicated loss of strength of not over 25 per cent as tested cold after fire exposure. When not reinforced, failure of the covering due to shrinkage effects took place before the end of the fire test."

## MICROSCOPIC EXAMINATION OF GYPSUM

The uses of gypsum are rapidly extending. The mineral is found in very large quantities in sedimentary formations of which it may be considered as one of the rocks. It is usually in such a position that it can be cheaply mined or quarried. It owes its value to the fact that it is a crystalline hydrate that can be easily dehydrated by heat; after which, on mixing with water, it crystallizes again with the water, becoming gypsum once more. The setting of plaster of Paris is simply the formation and crystallizing of gypsum from the partially dehydrated material.

To make plaster of Paris from gypsum, the raw material must be heated carefully, and not too long. Good plaster of Paris still contains about one-fourth the water of the original gypsum, and from the standpoint of the chemist it is called "hemihydrate." In this condition the substance can quickly combine with the water of which it has been deprived in the heating process. But if gypsum is completely dehydrated, it combines with water very slowly so that the product, called "artificial anhydrite," is useless for the purposes for which plaster of Paris is employed. At the same time, anhydrite is harder than gypsum, and not so easily dissolved in water. Keene's cement is mostly artificial anhydrite.

Raw gypsum contains, in addition to the principal substance, more or less quartz, anhydrite, calcite, and clay. As the quality of gypsum products is influenced by the impurities, it is desirable to have a rapid method of determining their quantities. In an appendix to the Report of Committee C-II on Gypsum, to be presented at the meeting of the American Society for Testing Materials at the meeting at Atlantic City on June 25-29, Mr. Esper S. Larsen describes a method founded on the use of the microscope, preferably of the petrographical model. When a thin slice of gypsum or some of the powdered mineral is examined as in the determination of rocks by the optical properties of the mineral constituents, it is easy to pick out the particles of quartz, anhydrite, calcite, and clay, and even to determine their quantities roughly, by counting the grains, estimating sizes, and calculating weights. It is possible in this way to determine the proportion of anhydrite in gypsum to within 0.5 per cent in samples containing less than 5 per cent and to within 1 per cent in samples containing 10 per cent. The time required is from a few minutes to one hour, depending on the care taken and the number of slides examined. Details of the method are given in the paper quoted.

## BARYTES

The principal uses for barytes after washing and grinding are as an inert pigment and filler in paint, paper, linoleum, oilcloth and rubber manufacture, and in the preparation of lithopone and a number of chemicals. The most important of such chemicals, other than lithopone, are: barium binoxide (used in preparation of hydrogen peroxide); barium chloride (used by pressed brick and by rubber manufacturers to neutralize sulphur content); barium chloride (used in battery plates, and as a mordant by dry-color manufacturers, and in tanning leather); barium nitrate (used in munitions and in making 'red fire' (used in barium sulphate precipitated, or 'blanc fixe' (used in rubber manufacture; for painting on interior steel or battleships and other sea-going vessels; also as a detector in taking X-ray pictures of the human body).

More than half the total tonnage of barytes utilized in the United States is in the manufacture of lithopone. This is a chemically-prepared, white pigment containing about 70% barium sulphate and 30% zinc sulphide, and is one of the principal constituents of "flat" wall paints now so extensively used in office buildings and hospitals, replacing both paper and calcimine wall finishes. Present quotations for barytes vary from \$5 to \$9 per ton, crude, f.o. b. rail-shipping point, depending on quality. Most barite has to be washed and acid-treated to remove iron stains or other impurities before being suitable for paint use.

The mill of the Geduld Proprietary on the Rand, which was formerly equipped with 100 stamps and 8 tube mills with a capacity of 500,000 to 600,000 tons per annum, has now a capacity of 800,000 tons per annum, due to the recent addition of 40 stamps and 5 tube mills. The ore is now to be ground more finely.

Though the cost of coal in Australia has not been reduced, two of its largest industrial works, the mines, mills and smelters dependent upon the ore of Broken Hill and the associated iron and steel works at Newcastle, have recommenced operation on a reduced scale.

# CHROMIUM\*

ITS OCCURRENCES AND USES

By HENRY BAILEY, M.I.M.M.

In common with many of the lesser-known metals, chromium in an unalloyed condition has found few uses in the Arts. In the form of alloys, however, it is being increasingly used, new applications being constantly discovered, so that possibly in the future it may rank as one of the most important alloying metals.

The most popular alloy of chromium is that produced in combination with steel to the extent of about 12 per cent., and constitutes the metal used in the production of stainless cutlery. As the knowledge of the heat treatments necessary for the manipulation of such alloys is extended, then utilisation for purposes other than cutlery is only a question of time, and an age of rustless steel inaugurated. Pure metallic chromium somewhat resembles iron in appearance, but is brighter and has a white colour; it is harder than glass, has a specific gravity of 6.92, and a melting point considerably higher than platinum; combined with a small percentage of carbon, its melting point is much lowered and its hardness increased to such an extent that it can only be cut by the diamond.

## The Raw Material

Chromium has not been found in the free or native state, the principal raw material from which it is derived being the mineral chromite or chrome iron ore, in which the chromium oxide exists in combination with iron oxide. This mineral is fairly widely distributed in nature, and doubtless supplies will keep pace with the increasing demand. Another ore of the metal is crocoisite, a chromate of lead. This, however, is not sufficiently plentiful to be a commercial source of the metal.

Many minerals derive their colour from the presence of small amounts of chromium, and this is true in the case of the emerald and ruby.

Chemically, chromium resembles iron, two series of salts being obtainable from two principal oxides, each series having a value commercially. Chromium sesquioxide is of a fine green colour, and, in addition to its being the source from which the pure metal may be obtained, is the valuable pigment known as chrome green. It is also used in the preparation of coloured glass, enamels, and porcelain, imparting to them a fine green tint.

## Chromium Trioxide

Chromium trioxide is red in colour, and being of an acid nature forms the basis of a series of salts known as chromates and bichromates, and in its hydrated form constitutes the chromic acid of commerce. The bichromates of soda and potash are very largely used in dyeing and for many purposes where a compound in which the oxygen present is easily available is required. For the preparation of the pure metal the purified sesquioxide is used, and may either be reduced by carbon in the electric furnace, the resultant metal containing some carbon being further treated until

all carbon is eliminated, or the reduction may be made by the "Thermite" process, the sesquioxide mixed with powdered aluminium being ignited, the resulting metal having a high degree of purity. For the purpose of chrome steel manufacture, pure metallic chromium is rarely required, being much too expensive for the purpose, the present price being somewhere in the neighbourhood of 5s. per lb., a more suitable and less expensive alloy known as ferro-chrome containing from 60-70 per cent. of chromium in combination with iron and produced directly from the ore chromite being used.

For the production of ferro-chrome there are two methods available, the "Thermite" method and the electric furnace reduction process, each of the two processes being used as circumstances and requirements dictate.

## The "Thermite" Process

In a great many instances the alloy maker and, more particularly, the steel alloy maker, calls for a metal with a high percentage of chromium free from carbon and with low percentages of other impurities, and to meet these conditions the "Thermite" method must be adopted, although the cost of production is necessarily higher than that of the electric furnace product.

In the "Thermite" process advantage is taken of the great affinity possessed by aluminium for oxygen, so that if a crushed oxide ore is mixed with powdered aluminium and the mixture ignited, a very intense heat is generated by the reaction, and a fused bath of metal results. Unfortunately with chromite the reaction does not take place with the simplicity one would expect from similar reactions with other oxides; not only does the mixture refuse to satisfactorily ignite, but even when once started the reduction does not proceed with sufficient vigour to maintain the mass at a sufficient temperature to give a fused metal which separates easily from the simultaneously formed slag, and it is essential to produce a satisfactory product and a high percentage recovery to incorporate with the ore mixture a percentage of an active oxidising agent; the mixture naturally increases the cost of the resultant metal, as not only has the cost of the incorporated oxidiser to be considered, but also the additional aluminium required to combine with the added oxygen.

## Some Experiments

The writer, in conjunction with Mr. George Dickie, of Luton, did a considerable amount of work on the nature and extent of the oxidiser required to get a nearly perfect reaction, and evolved a scheme of operations which gave a high-grade carbon-free ferro-chrome from an ore of somewhat poor quality. The chromite operated on contained an excess of iron oxide in admixture in addition to a considerable percentage of silica, with a result that, reduced direct with aluminium, the ferro-chrome produced was too

\* From "Raw Materials Review," London.

low in chromium and, moreover, contained an unduly high percentage of reduced silicon. A preliminary concentration of the chromite was conducted on lines similar to that in use in the mines for the recovery of tin, the roasted ore being run in the form of a thin pulp on to a "buddle," the chromite having a higher specific gravity than the associated impurities was obtained as a head, the impurities giving a tailings low in chromium. The concentrated chromite was dried, mixed with the necessary aluminium and oxidiser, and when ignited with a fuse was vigorously reduced, producing the required grade of carbon-free metal which separated easily from the fluid slag. It is of interest to note that this slag, which consisted mainly of aluminium oxide or artificial corundum, was freely interspersed with minute crystals of synthetic ruby.

For the production of ferro-chrome in the electric furnace it is advisable to conduct the operation in two stages. The first stage consists in fusing the chromite mixed with carbon as a reducing agent together with the requisite fluxes in an electric furnace to produce a metal having a fairly low melting point and a comparatively high percentage of carbon. This high carbon ferro-chrome is then transferred to an electric refining furnace, where it is fused with such fluxes as experience dictates until a metal is obtained containing such a percentage of carbon as the steel-maker demands.

Chrome steel has long been used in the manufacture of armour-piercing projectiles, and usually contains about 2 per cent. of chromium; it is also used for certain rock-crushing machinery and for safes. Alloyed with nickel and other metals a very valuable series of acid-resisting alloys have been obtained, and it only remains for a comparatively cheap process for producing chromium or ferro-chromium from its ores to be discovered to render it available for the construction of much larger units than is now practicable.

### CHROME-ORE PRODUCTION IN RHODESIA

A feature of mineral production in Rhodesia during the later months of the year 1922 has been the expansion of the chrome-ore industry. The total production of chrome ore in 1921 was 50,188 tons, and in 1922 94,475 tons. The highest production for any single month was in November, 1922, when 24,814 tons were mined.

For some years past Southern Rhodesia has been one of the principal chrome-ore producing countries in the world, and, as in the case of various other minerals, the demand occasioned by the European war resulted in a very marked increase in output. Between June, 1921, and May, 1922, the demand dropped to such an extent that practically all the mines in Rhodesia ceased producing. Since May, 1922, there has been a revival in the demand for chrome ore on a larger scale than ever.

The principal producers of chrome ore in Rhodesia are associated ventures styled the Rhodesian Chrome Mines (Ltd.) and the Rhodesian Metals Syndicate (Ltd.). These companies hold claims in other parts of Rhodesia than the Selukwe district, where the principal deposits are located, and such is the variety of their deposits that they are able to supply almost any grade, both hard and "fines." The deposits are very extensive and mining costs are comparatively low. The present price of Rhodesian chrome ore (50 per cent) is from £5 to £6 per ton. —Commerce Reports.

### INHERENT EFFECT OF ALLOYING ELEMENTS IN STEEL

The sciences of chemistry and physics have greatly contributed to the advances in the manufacture and treatment of steel. Their application has converted the steel industry from a rule-of-thumb business to one in which the properties of the product can be controlled with some degree of certainty, if not yet perfectly. By chemical analysis, uniformity of the raw materials is guarded, and by the same means the composition of the product is watched. The physicist and engineer have contributed methods of measuring high temperatures, the use of the microscope to examine polished or etched surfaces and so to examine the structure minutely and refined methods for measuring hardness, brittleness, strength and magnetic properties. But it is by exploration in a region lying between chemistry and physics, namely in physical chemistry, that the greatest amount of information has been brought to light regarding the structure and properties of steel.

At a meeting of the American Electrochemical Society (New York, May, 1923), B. D. Saklatwalla, General Superintendent of the Vanadium Corporation of America, presented a paper with the above title in which he gave a clear and informing account of what is known about the inner effect of alloying elements in steel. He also suggests a direction in which knowledge is incomplete and awaiting further research.

Steel, according to Mr. Saklatwalla, is, at the ordinary temperature, a heterogeneous conglomerate of various crystalline constituents cemented together by a medium of imperfectly known physical state. This cementing material binds the crystals together.

#### Crystal Growth

The physical properties of steel depend then largely upon the shape, size, and arrangement of these crystals and upon the quality of the cementing material. The growth of crystals, as is well known, is influenced by a number of factors, including rate of cooling and the presence of substances other than those forming the crystals. Other things being equal, the slower the cooling, the larger the crystals. Substances of a colloidal nature, such as glue or white of egg, retard the growth of crystals, and may also cause unequal growth on different surfaces, so that a substance that will form, under favorable circumstances, granular crystals may under these hampering conditions grow long or branching crystals.

Another interesting property of growing crystals is that as they form they tend to reject impurities. A familiar example of this is the well-known fact that ice forming over salt water has very little salt in it. On the other hand, if the impurity is closely related to the crystallizing substance, the latter may incorporate the former in its crystals, in some cases indefinitely, in others to a limited extent.

#### A Problem for the Researcher

Mr. Saklatwalla makes use of these and other known facts in the growth of crystals to explain the effect of alloying elements on steel. The main constituents of ordinary carbon steel are, from this standpoint, iron and iron carbide; and the properties conferred upon iron by carbon, making it steel, are to be explained by the interaction of iron and iron carbide. But the explanation is still incomplete, because, as suggested by Mr. Saklatwalla, there has so far been no thorough investigation of the properties of iron in the liquid condition at its point of solidification. The iron molecules have certain properties at that point, including those that make steel hard. These are progressively lost as the iron solidifies and cools.

If, however, the iron is cooled suddenly enough, the molecules are prevented from losing or changing these properties. The presence of iron carbide decreases the rate at which the change takes place, so that while pure iron becomes very slightly harder even when suddenly cooled, steel acquires the property of hardness under those conditions.

"The inherent physical effects of chemical elements undoubtedly start in the liquid stage, and, as the physical properties of the liquid from which crystallization takes place determine to a great extent the properties of the crystallized solid, the influence of the alloying elements should be studied in relation to the physical changes occurring prior to or during solidification. While undoubtedly, by the proper thermal treatment, much can be achieved in solid steel, yet it will be right to assert that the inherent characteristics of the steel are defined up to solidification in the ingot stage, and that all later thermal manipulations are of secondary importance." This emphasizes the importance of studying alloy steels from the point of view of the relation of their composition to the properties of the alloys at the point of crystallization, as well as throughout that process. Up to the present, research has been directed rather to the properties, composition, and minute structure of solid steel.

### The Alloying Elements

The influence of alloying elements on the crystallization of iron is twofold. The alloying element is taken into the crystals of iron up to a certain maximum, beyond which it is rejected and remains in the cementing material between the crystals. It modifies the properties of the iron crystals and also those of the cementing material between them. It not only influences the rate of growth of the iron crystals but may cause them to grow faster in one direction than in others and so to form long fibres or branching growths, conducive to strength in the steel. The slow growth has the same effect as quick cooling in preventing coarse-grained structure caused by large crystals.

The cementing material may be largely of the same composition as the crystals. It is a well-known fact that the presence of foreign elements lowers the crystallizing temperature. In the process of crystallization these materials are concentrated in the liquid part. If the cooling is rapid enough the iron along with the foreign element forming this liquid may become solid without crystallizing, thus giving a structure to the whole analogous to that of porphyry, where the fine-grained material between the crystals of feldspar, quartz, etc. may be largely of the same composition as the crystals.

The presence of an alloying element may increase or decrease the power of the growing crystal to incorporate impurities and so decrease or increase the amount of these impurities left in the cementing material. This may so affect the properties of that material as to profoundly influence the physical properties of the steel dependent on those of the cementing material (called by Saklatwalla "intercrystalline medium"), such as elastic and endurance limits.

### A Useful Theory

The author uses the rejection of the alloying element by the growing crystals to account for the non-corrosiveness of chrome-steel, pointing out that this property shows itself markedly only in steel that has at least 10 per cent of chromium. At some point below that amount, the iron crystals are capable of incorporating all the chromium, but with 10 per cent to 14 per cent enough chromium is rejected to coat the surfaces of the crystals and so protect them from corroding agents.

In a similar way he accounts for the special properties of 3.5 per cent nickel steel and 12 per cent manganese

steel, these amounts being necessary in order to saturate the iron crystals and at the same time leave enough over to improve the properties of the cementing material. On the other hand the growing crystals reject any surplus of sulphur and phosphorus and these elements so change the properties of the cementing material as to produce the well-known effects in the steel.

### Inter-molecular Cohesion and Hardness

The relation of surface tension to the molecular composition of steel is used to throw light on hardness and other properties bound up with it. The hardness of a metal is generally increased by the addition to it of another metal. A familiar example of this is the use of copper to harden gold. Hardness is in part a measure of the difficulty of separating molecules from each other. The introduction of a second metal provides for the well-known attraction of unlikes and thus increases the strength of cohesion among the molecules. A study of this subtle property, surface tension, due to molecular attraction, familiar results of which are seen in the roundness of raindrops and dew and the rise of water in very small tubes, may throw light on many obscure steel problems. "Hence we see the importance of a study of the surface tension qualities of a metal in the liquid state, and the influence of foreign elements on the surface tension, in order to arrive at engineering merits after solidification."

Future advances in the metallurgy of steel will come largely from the application of methods of research dependent on the use of the highest scientific knowledge at our command. Much has already been accomplished in this way, but much remains to be done. As producers of nickel, chromium, and molybdenum ores, Canada should take part in the necessary research.

### TANTALUM IN COMMERCE

The current issue of *Industrial and Engineering Chemistry* contains a description of the preparation, properties and uses of the metal tantalum. It is best known for its former use as the filament in incandescent electric lamps, and between 1903, when the first process for making tantalum wire, and 1911, when it was superseded by tungsten filaments, millions of lamps fitted with tantalum wire were made and used.

The most common of tantalum-bearing minerals is tantalite, the combined oxides of tantalum, iron and manganese. From this the pure oxide of tantalum is separated with comparative ease, and the oxide is reduced to the metal in a specially constructed vacuum furnace. The metal is not attacked by acids except hydrofluoric, nor by caustic alkalis. It combines readily with hydrogen, oxygen, or nitrogen, being capable of taking up 740 times its own volume of hydrogen. The pure metal resembles platinum in appearance, has a melting point of 2850° C., a specific gravity of 16.6, and is tough, ductile and malleable, its tensile strength reaching 130,000 lbs. per square inch. It oxidizes in the air at a comparatively low temperature.

Numerous chemical and industrial uses are suggested for tantalum, making use of its chemical inertness. The most obvious use seems to be as wire, sheet or ribbon in radio sending and receiving apparatus, where its capacity for absorbing gases would make it very useful in the vacuum tubes. It has also some electrical characteristics that may make it very useful.

# THE MINING DISTRICTS

BY THE JOURNAL'S CORRESPONDENTS.

## NORTHERN ONTARIO

**Dome Report.** — The annual report of the Dome Mines for the year ending March 31st, which has just been issued shows that a total of 363,000 tons of ore were milled and the recovery amounted to \$4,287,935, an average of \$11.79 a ton. This grade compares with \$1.80 for the preceding year and the gross recovery shows an increase of \$1,300,000. The profit for the year was \$2,426,856, as compared with \$1,245,000 in the preceding year. The total quick assets amount to \$2,677,821, and there is also a Dividend Assurance Fund of \$1,026,839. The issued capital now stands at \$4,290,003, and the surplus as at March 31st is \$1,126,693. Compared with the preceding year the report is an exceptionally encouraging one; but there are some features that indicate the possibility of the hanging-wall ore-bodies being cut off below the 12th level. The report indicates that the porphyry is dipping to the north at a comparatively flat angle and points to the possibility of this cutting off the sedimentary rock in which the ore-bodies are found. It is, however, too early as yet to make any definite statement regarding the possibility of ore-bodies at greater depth, and it may well be that other deeper ore-bodies will be found. To offset this one discouraging feature, the developments toward the Dome Extension have been very favorable and have opened up ore on the 12th level. In this section of the company's property, the porphyry is dipping to the south and the possibilities for substantial ore-bodies are very encouraging. The production, profits and amount of development work done were less than would have been realized had it not been for the power shortage that occurred during five months of the Dome's fiscal year. Due to the same factor, the cost per ton was greater and was \$5.25 as compared with \$4.56 in the preceding year. With the notice calling the annual meeting has been sent a copy of the by-law it is proposed to pass. This by-law provides for the transfer of the assets to a new corporation, with the capital stock divided into shares of no par value. One feature of the by-law which no one seems to understand, is the fact that out of the assets of the present company there shall be reserved from the transfer, cash and liquid securities not to exceed \$2,000,000, which shall be retained by the company and paid and distributed from time to time as the directors of the new corporation shall decide, in the same manner and proportions as dividends shall be payable to shareholders of the new corporation. This is one of the proposals that has resulted in the opposition to the present management which it is expected will develop at the annual meeting. Officials of the company state that they do not anticipate any trouble, but it is learned on good authority that a very large block of stock will be represented by the opposition.

**No Power for Vipond.** — The officials of the Vipond have notified the shareholders that the power com-

pany propose to discontinue power service to the mine commencing June 1st. This action was taken on account of the scarcity of power and prior contracts held by the large producing mines of the district. The directors first announced that they would close the property down, but on account of the very encouraging discoveries that have been made during a comparatively recent period, it was decided to operate by steam for a short time in order to gain information which would permit the directors to proceed with the equipment of the mill. The officials state that a new ore-shoot has been developed on the 400-foot level for a length of 470 feet, with an indicated average for that distance of \$18.20, over 62 inches, the vein, however, being wider than the drift. The same vein has been cut on the 300-foot level, and gives an average of \$15.55 for the length of 41 feet developed. A more important discovery has been made on the 1000-foot level, close to the Hollinger line, where a vein showing a value of \$28.00 over 4 feet was cut.

**Continued Power Shortage.** — The general manager of the Northern Canada Power Company has stated that that company will be unable to supply power to any except the three big mines of Porcupine, the Hollinger, Dome and McIntyre. He has also stated that it will be a year before power can be supplied to any other companies. Contrary to the general expectation, there will be no change when the Sturgeon Falls plant is in commission, as in view of the expected shortage later on, it is necessary to conserve the water available. There is a good deal of disappointment felt over this, and there is also a feeling that the three big mines should not be allowed to monopolise the power supply. The future of the district lies not only with these properties, but also with other new properties that may be developed. The three operating companies are financially able to stand any loss that may occur until such time as power is available from the new Quinze plant; but it is a different proposition with those companies that are not producing, and the added expense of generating steam power or closing down may prove to be a very severe handicap. Any property that gives real promise can be financed without much difficulty at present, but conditions may change within the next eighteen months and it may not be so easy to arrange for funds. The Great Northern Power Company expects to be in a position to deliver power some time this month, but its power is 60 cycle, while that of the Northern Canada is 25, so that a switch from one to the other could not readily be made. It is understood that the Hollinger, within a short time, will call for bids on its Abitibi development, where it is expected that 20,000 h.p. will be generated.

**Kirkland.** — During the month of May production from the Teck-Hughes Gold Mines amounted to \$103,000, which is the largest monthly output in the history of the company.

At the Lake Shore work is under way on the new mill, which it is hoped to have in operation by fall. The new steel head frame is being erected and will be completed this month. The old mill building is being extended and the foundations for the new crushing plant are also under way. The shaft is now down 760 feet, and will shortly reach the 800-foot level, where lateral development will be commenced.

An official report of the new discovery on the Kirkland Lake Proprietary states that a well mineralized fracture has been cut 200 feet south of the main shaft, and shows an average of \$7.50 over a width of 59 inches and for a length of 26 feet, the length that had been driven at the time the report was issued. The management state that the discovery is likely to be important.

The new mill at the Argonaut has been started at about fifty tons a day. The mill has a capacity of two hundred tons, and it will gradually be brought up to this.

A statement of the Kirkland Lake Gold Mines show that for the four months ending April 30th, there was an operating profit of \$8,423. This, however, was before allowance was made for interest and depreciation. Interest alone amounts to \$3,000 a month. Notes payable to the Beaver Mine amount to \$382,400 and accrued interest amounts to \$121,864. The report holds out encouragement regarding the new vein that has been discovered in the lamprophyre and has been proven on the 700, 800, 900 and 1000-foot levels.

**Cobalt.** — An interim report of the Beaver Mines shows that on December 31st last there was cash on hand of \$128, inventory ore, and bills receivable of \$15,000, while bills payable amounted to \$6,000. The Beaver investment in the stock of the Kirkland Lake Gold Mine amounts to \$342,185 and there is a further sum of \$491,865 owing to the Beaver from the Kirkland Lake, consisting of notes and accrued interest.

The Coniagas Company, which has taken over the Beaver on a profit sharing basis, has been overhauling the mill and shaft house and installing new equipment in the mill in order to increase the capacity. It was expected that the mill would be able to start about the middle of June, but it is now found that it cannot be started until some time in July. In the meantime underground work is being continued and a substantial tonnage of ore is being broken ahead of the mill. The Coniagas' expenditure on the Beaver up to April 30th amounted to \$51,482.

## NOVA SCOTIA

**Union Convention.** — The U. M. W. of A. is gathering its forces for a convention at New Glasgow at an early date, when they will discuss the re-opening of the agreement with the Dominion Coal Company for the purpose of trying to attain the 1921 rates. The Company has already refused to discuss this matter with them, further than to say that the agreement will not be re-opened, as all coal contracts have been based on the current wages, and delivery under a higher wage schedule would result in heavy financial loss. There is still much speculation as to the report of the commission of American officers, who visited the district. Knowing that the executive of the International openly state that they honorably stand by all agreements, there is little apprehension of an unfavorable report, without which

it is thought the miners would not attempt to force a return to the 1921 rates of wages. At the same time the forces are being mustered under the battle cry of "Now or Never" by the district executive, who are no doubt anxious to retain their hold on the miners. Your correspondent believes that faith will be kept and that the Nova Scotia miners will loyally stand by their agreement.

**Examinations in Progress.** — The annual Mining and Colliery Engineering examinations are being held in Sydney. There is the largest attendance in the history of Mining schools, the number sitting being 150. As these are all young men, it is a wholesome reflex of the ambitions of the younger generation growing up round the collieries. As every opportunity is afforded men with certificates to rise in the mining and engineering professions, the stimulus to acquire knowledge is strong, and the aims of the students are shown in the increased numbers offering for examination. Among those who looked in on the classes at the examinations was Mr. T. J. Brown, Deputy Minister of Mines. The broad smile of Mr. Brown alone will do much to cheer many of the candidates, wrestling with complex problems of which many of them know more by practice than by theory.

## BRITISH COLUMBIA

**Indian Mines.** — G. D. B. Turner, managing director of the Indian Mines Ltd., Portland Canal District, has returned to Victoria after spending some weeks on his property. Transportation problems, he says, are now his chief concern. New machinery recently installed is giving satisfaction and progress is being made in driving the two tunnels that are opening up the ore-body.

**Dome Mountain.** — The mining property of the Dome Mountain Gold Mines Ltd., twenty-three miles north of the town of Telkwa on the Grand Trunk Pacific Ry., is reported to have been bonded by the Guggenheim interests. J. D. Galloway, government mining engineer, is said to have inspected and made a favorable report on the prospect, the gold content of the ore being high. Mining equipment and camp accomodation are being provided. H. Lee is in charge of the work.

**Copper Mountain.** — L. R. Clapp, assistant general manager at Anyox for the Granby Consolidated Mining & Smelting Co. Ltd., will have supervision of the Company's prospective operations at Copper Mountain and Allenby. This mine and plant, which is being taken over from the defunct Canada Copper Co. Ltd., by the newly organized Allenby Copper Co., will be controlled from Anyox, with Mr. Clapp as resident manager, his headquarters being either at the mine or at Allenby. H. S. Munroe, general manager of the Granby Co., states that the Copper Mountain property will be producing very soon, but points out that some sixty days will be required to put the railway roadbed in condition and to make repairs at the mine and the concentrator. It is expected that between five and six hundred men will be given employment.

**New Granby Property.** — The Granby Company has acquired control of the Sultana Group of mineral claims on Boulder Creek, about 125 miles east of Prince Rupert on the Canadian National Ry. There are fourteen claims containing a large body of copper-

leadings are with values in gold and silver. Active development is promised.

**Ore Shipments from St. Eugene.** — The St. Eugene Mine, Moyie, ten years ago was the leading silver lead producer of the Consolidated Mining & Smelting Co. of Canada, and now has made its first shipment of ore for several years. Fourteen tons were contributed by the St. Eugene, to the total of 6,701 tons received at the Trail smelter during the week May 15 to 21. The detailed shipments follow:

|                                |       |
|--------------------------------|-------|
| Alameda, Alameda               | 45    |
| Company Mines                  | 6,022 |
| Henderson Gp. Smithers         | 21    |
| Knob Hill, Republic, Wn.       | 106   |
| Lone Pine, Republic, Wn.       | 162   |
| Quilp, Republic, Wn.           | 53    |
| Roschbury Surprise, New Denver | 49    |
| Silversmith, Sandom            | 188   |
| Standard, Silvertown           | 41    |
| St. Eugene, Moyie              | 14    |

6,701

**Placer Gold Reported.** — A placer gold discovery of some importance is reported on Six Mile Creek near Prince George. News of the find has created a stir in the little interior British Columbia community.

**Cariboo.** — There will be plenty of water in the Cariboo for hydraulicking work. Information received from various sections in which operations are planned, notably Cedar Creek, indicate that conditions are better than last year and that a good season is assured.

**Students Visit Mines.** — A large party of students from McGill University, Montreal, recently made a tour of the chief mines of the Kootenays. Under direction of Prof. J. W. Bell the party went over the Trail smelter, the copper mines of Rossland, and other active properties. They previously had visited the Sudbury nickel mines and the coal mines of Coleman, Alberta.

**Stampede From Dawson.** — News of the discovery of a new silver ledge at Happy Creek, 40 miles south of Dawson, recently resulted in a midnight stampede out of Dawson City.

**Fuel Board's Report.** — The interim report of the Dominion Fuel Board, of which Charles Camsell, Deputy Minister of Mines, Ottawa, is chairman, has created much interest in western Canada. The consensus of opinion is that Mr. Camsell and his confreres have grasped the essentials and made some good suggestions. In the 10-year period ending 1921, Canada's bill for imported coal exceeded \$580,000,000 and in this connection the Fuel Board urges the adoption of the several measures for national fuel economy that have been discussed during recent months.

**Alberta Coal Operators to Confer.** — Coal operators of the Province of Alberta, and others interested in the business in Western Canada, will hold a conference in Winnipeg during the month of June. They will discuss the shipment of domestic coal from Alberta to Ontario. The Governments of each of the Prairie Provinces will be represented and there will be in attendance representatives of the chief dealers of Ontario. Sir Henry Thornton, president of the C. N. R., is expected to be present.

**New Coal Association.** — All the coal mines in the

Canadian prairie country north of the Red Deer River that are producing domestic fuel have joined the Northern Alberta Coal Operators' Association. The new organization includes in its membership some twenty-five active mines and the management of each of these undertakes to deal only with the Canadian Federation of Labor. A significant clause in the charter granted Locals by the latter body is that forbidding affiliation in any form with the United Mine Workers of America. The president of the Northern Alberta Coal Operators' Association is C. W. Leonard, of the Chinook Coal Co., and the secretary C. W. Crupples, of the Great West Coal Co.

**Coal in Stanley Park.** — Coal measures are reported within the boundaries of Stanley Park, Vancouver. The result has been a spirited controversy, through the press, in the City Council meetings, and elsewhere, between those who would sacrifice the beauties of the Park to industry and those to whom the natural grandeur of unspoiled nature is nothing as compared to industrial progress. Of course it has been a "tempest in a teapot" for it is more than doubtful whether the coal in question would be found when explored to be of such quality and thickness as to warrant exploitation; but while it lasted the fight was quite exciting. The artistically inclined, however, have won out. The Stanley Park coal deposits will remain undisturbed for the time at least, and the stacks and smoke of collieries will not deface the stately Douglas firs of one of the finest natural parks of the Pacific Coast.

## SULPHUR IN PETROLEUM PRODUCTS

Some Mexican crude petroleums run as high as five per cent sulphur, but in the crudes produced in the United States the sulphur content is rarely greater than one per cent, and in the majority of crudes is below five-tenths of one per cent, according to D. B. Dow, assistant organic chemist, U. S. Bureau of Mines. This sulphur may be present as dissolved sulphur, colloidal sulphur, hydrogen sulphide, or sulphur deviations of hydrocarbons. The study of these forms of sulphur is very complex, and unfortunately little information covering the chemistry of sulphur in petroleum is available. In the distillation of crude oil, either in the refinery or laboratory, sulphur generally is present in all the distillates, as well as in the residuum. Its occurrence in natural gas is quite common and consequently it is often found in gasolines derived from natural gas. Sulphur compounds have various objectionable characteristics. Distillates from certain crudes, such as those from Lima, Ohio, and Petrolia, Canada, have extremely bad odors and can not be used until desulphurized. Mexican crudes and distillates often contain notable quantities of hydrogen sulphide. As this is a toxic gas, it has been the cause of many cases of poisoning, some of which have proved fatal. Illuminating oils containing sulphur in appreciable amounts often produce poor light and are thus unsatisfactory. The use of oils containing elementary sulphur or hydrogen sulphide is objectionable with certain metals, such as copper, because of the corrosive action of such oils on these metals. Gasoline discolored by sulphur compounds often becomes quite yellow and may have the appearance of an inferior motor fuel containing components of low gravity and high end point. This appearance, of course, detracts from the price even though the gasoline may be satisfactory in use. The presence of sulphur in petroleum is therefore, objectionable, and products free from sulphur usually are more desirable. Information regarding the detection of sulphur in natural

gas gasoline and the treatment for the removal of certain sulphur compounds is given in Serial 2462, which may be obtained from the Department of the Interior, Bureau of Mines, Washington.

### SWISS CARBIDE OUTPUT

The possible production of the seven Swiss carbide factories is close upon 120,000 tons of carbide yearly, of which, with the manufacture of manures, only about 10,000 tons are used in Switzerland itself, all the rest having to be exported. The export crisis and the import prohibitions, together with the high duties of several countries, have seriously affected the Swiss carbide factories and have led, says the "Chemical Age," to the closing down of several large factories. The export of carbide, which amounted in 1919 to 37,000 tons, with a value of 20.2 million francs, fell in 1922 to 9,200 tons only, valued at 2.2 million francs, the chief purchasers being Belgium and Holland.

### RUSSIAN ASBESTOS

The pre-war annual export of asbestos from Russia was about 11,000 tons, or two-thirds of the total output. During the war and revolution, up to about 1920, Canadian asbestos largely replaced the Russian on the European market. Since 1921, however, the export of Russian asbestos has begun to revive. In the first eleven months of 1921, says the "Russian Information and Review," 1,600 tons were exported, and in the same period during 1922, 1,800 tons were sent abroad. According to the estimates of the Urals Asbestos Trust, it should be possible to export nearly 5,000 tons annually in the near future, but taking into account the difficulties of transport, and the competition of Canada, it is scarcely likely that this figure will be reached during 1923.

### MANGANESE ORE FROM BRAZIL AND RUSSIA

Quantities of manganese ore are now being shipped by water to Birmingham, Ala., from Brazil. The United States Steel Corporation recently paid duty to the Government amounting to \$104,250, and an estimate is made that in the next three months not less than \$250,000 will be paid in duty.

Over 800,000 tons of Russian manganese ore used to be exported annually in pre-war days. During the war this was largely replaced on the European market by Indian and Brazilian ores. But these ores cannot compete in quality with the better grades of the Russian product, says "Russian Information and Review," and within the last eighteen months considerable interest has been shown in the Russian ore. In 1921 the ore exported only amounted to 3,100 tons, while in 1922 it rose to 38,700 tons. The amount of high-grade Nikopol manganese ore to be exported during 1923 has been fixed at 48,000 tons, and of the total production there may be as much as 75,000 tons available for export.

**CANADIAN MINING ENGINEER**, holding responsible position in United States, desires opening in Canada. Thoroughly familiar with all details of mine development and successful record in mine operation. Must give present employers reasonable notice. ### PURCHASE OF GOLD ORES

The attention of prospectors and others is drawn to the provision in the Mining Act of Ontario authorizing the Department of Mines to purchase parcels of gold ore taken out by prospectors and others in developing or working mining claims. Arrangements have been made by which such parcels of gold ore, whether large or small, will be accepted by the Temiskaming Testing Laboratories at Cobalt, and paid for according to the schedule provided for the purpose. The Laboratories are operated under the auspices of the Department of Mines.

This offers a first class opportunity for testing the value of ores on a large scale, and also of turning ore of good quality into money for carrying on further development work. By special arrangements, on less than carload lots, freight rates on the T. & N. O. Railway are reduced 50 per cent.

The Laboratories are also equipped for working out the best methods of treatment for gold or silver ores of a refractory or unusual character.

Full information as to treatment charges, schedule of payments, etc., can be obtained from the undersigned, or from A. A. Cole, Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

THOS. W. GIBSON,

Deputy Minister of Mines.

Toronto, 12th March, 1923

# PROVINCE OF QUEBEC

## MINES BRANCH

Department of Colonization, Mines and Fisheries

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, etc.

### MINISTER OF COLONIZATION, MINES AND FISHERIES, QUEBEC

**MINER'S CERTIFICATES.** First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is \$10 and is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

**WORKING CONDITIONS.** During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

**SIX MONTHS AFTER STAKING.** At the expiration of six months from the date of the staking, the prospector, to retain his claim, must take out a mining license.

**MINING LICENSE.** The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year, and a fee of \$10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days' labour on each fifty acres.

**MINING CONCESSION.** Notwithstanding the above, a mining concession may be acquired at any time at the rate of \$5 an acre for SUPERIOR METALS, and \$3 an acre for INFERIOR MINERALS.

The attention of prospectors is especially called to the territory in the North-Western part of the Province of Quebec north of the height of land, where important mineralized belts are known to exist.

**PROVINCIAL LABORATORY.** Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, Montreal, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

**HONORABLE J. E. PERRAULT,**

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

## Another Typical Dodge Job

The illustration above shows a fine example of the work done in our Foundry and Engineering shops.

It is a split Cast Iron Double Arm Fly Wheel Pulley.

Its diameter is 216 in., its face 45 in., and its approximate weight 21 tons.

It was made to specifications for a big Saw Mill and was shipped on time.

We invite correspondence from mill superintendents who wish big work done in a big way by an organization whom they can rely upon to turn out work accurately, efficiently and on time.

# Minerals

PROVINCE OF ONTARIO

DEPARTMENT OF MINES

Hon. H. MILLS, Minister of Mines

## Mineral Areas.

Ontario, with its 107,262 square miles, contains many millions of acres in which the geological formations are favorable for the occurrence of minerals, 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver mines of Cobalt occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

## Economic Minerals.

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario:—actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluor-spar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, Portland cement, brick and tile, meet every demand.

## Mineral Production.

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1921 to be worth \$48,128,387, of which the metallic production was \$27,574,202.

The following figures show the rapid growth of Ontario's mineral industry by five-year periods since 1891:

| Year.         | Value.      | Year.         | Value.       |
|---------------|-------------|---------------|--------------|
| 1891 .. . . . | \$4,705,672 | 1906 .. . . . | \$22,388,383 |
| 1896 .. . . . | 5,235,003   | 1911 .. . . . | 41,976,797   |
| 1901 .. . . . | 11,831,086  | 1916 .. . . . | 65,303,822   |

## Dividends.

Dividends and bonuses paid to the end of 1921 amounted to \$23,140,734 for gold mining companies, and \$84,388,185 for silver mining companies or a total of \$107,528,919.

## Mining Regulations.

A miner's license costs \$5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of \$2.50 or \$3.00 per acre, depending on location in unsurveyed or surveyed territory.

## Assay Office.

The Provincial Assay Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

## Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

## A Bank That Is Always Near

The mining engineer — moving as he does from place to place — must needs utilize a bank which has branches conveniently located in mining centres.

The Imperial Bank, with 192 branches throughout Canada and

with special concentration in mining districts, offers distinct advantages to those engaged in the mining industry. Patrons of this Bank are never far from their bank accounts no matter to what part of the Dominion they may go.

Why not ensure adequate banking facilities by  
depositing *your* funds with this Bank?

## "STIRRING UP WILLY"

In the words of the gentleman of sable pigmentation, most of the scientific research that is being done in Canada "ain't."

That expresses it. We have had an ocean of talk—and the merest spoonful of performance. Notwithstanding the fact that enlightened Canadians recognize the profound and instant need of scientific and industrial research, nothing they have done or said seems sufficient to stir our Government to action. We are reminded of the Victorian "limerick" the concluding lines of which are:—

"Now, although the room grew chilly,

"No one cared to stir up Willy."

Of the small group of men of light and leading in public life who have consistently espoused the cause of research, Mr. Hume Cronyn, ex-M.P., is the most impressive. During last winter's conference, a meeting arranged by the Canadian Manufacturers Association, Mr. Cronyn showed that Canada's organized efforts to keep abreast of the times in scientific and industrial research are almost *nil* as compared with the United States, Great Britain, France, Sweden, and Japan. Japan has been a modern nation for less than half a century. Canada was settled by Europeans four centuries ago.

What, then, is wrong? Or, as Mr. Cronyn pertinently asks: — "Are these other nations, who are making "large expenditures on scientific research, chasing a "will-o'-the-wisp? Can this idea be a mere fad or "dream?... We are the only British Dominion which "has not actively taken steps towards the establish- "ment of a national research institute. Are all the "others out of step? Is Canada alone marching for- "ward?"

The Research Council, a notable aggregation of selected brains, has been of use. Its prime function, however, is to act in an advisory capacity to the Dominion Government. If the Dominion Government refuses to be advised, there is thought to be no recourse. But recourse there is. That recourse is an appeal to the source of all authority, the people. The means of appeal is publicity.

Occasional subsidized newspaper publicity has but an evanescent effect. If, instead of focussing attention on isolated (though interesting and profitable) researches, the Research Council were to concentrate every whit of its energy on convincing the public that the future of Canada depends upon research, that in-

dustrial progress is unthinkable without it, that some one must "stir up Willy", then the goal would be practically won. The gospel of research should be, must be, preached from our pulpits, taught in our schools, in our colleges, and fed in words of one syllable to the daily press. The "average citizen", the "man on the street", and the carrier of the dinner-pail must be taught that their welfare and the welfare of their children is bound up in the nation's support of research. Public consciousness, once awakened, will lead inevitably to action at Ottawa.

The stated scientific research does not appeal to the public imagination. Results do. There are numberless convincing results, modern instances, that may be quoted. Of these there are plenty that will strike keenly the ordinary citizen. Academic generalities will not serve the purpose. The public demands the sincere and unwatered milk of the word.

We can easily visualize the speedy erection of National Institutes, Bureaux of Standards, and the accomplishment of all and more than all that the Research Council dreams of, if the public be taken into its confidence. And this is to be desired, if only to dissipate the repellant atmosphere of academic aloofness that surrounds all such bodies.

## A COSTLY HABIT

Habit is a creature of fearful and wonderful power, controlling much even of modern engineering practice. Often investigation or scientific research is required to disclose the subtle rule of habit and the resultant waste of effort and material. In other cases habit reigns supreme, without let or hindrance, in the face of the whole community. One such habit is costing the taxpayers of Canada millions of dollars annually. We are paying "through the nose" for good roads, which are not good roads; they have shoddy surfaces.

It is a curious fact that, amidst all the discussion about the hundred and one features of a good road, one point, and that the most important of them all, has received scant attention. We refer to the chief ingredient of the wearing surface of any road — the stone that composes it, in whole or in major part. Upon the wearing quality of this stone depends the wearing quality of the road; yet how often is the quality of the stone considered seriously? So far as we have observed, the larger part of our "good" roads are surfaced with crushed limestone, used either as water-bound macadam, with bituminous binder or as

the aggregate is necessary. Only when it is the road side material is a rock of better quality used, and that is very seldom. Throughout the larger part of eastern Canada, limestone of various degrees of softness is the rock most readily obtained, so of limestone our roads suffer most.

What is the result of building a limestone wearing surface? In all cases it is wasteful. We have observed a new provincial highway whose macadam surface was destroyed by a moderate stream of traffic after six weeks of use. In this instance trap rock, brought to fill at an enormous expense that would add only a few per cent. to the total cost of the road, or even of the wearing surface alone, would have made a road capable of six years of wear. The cost of hauling, spreading and rolling the rock is the same in both cases, so why not build a surface that will last six years instead of six weeks?

Some of our asphalt and concrete roads are now old enough to demonstrate similarly the value of a hard aggregate. These "permanent" surfaces have in some cases been worn down for inches through their main constituent, limestone, where the use of trap rock, at only a slight advance in cost, would have made the investment genuinely permanent. The waste due to shoddy material in this case is not so apparent; still it presents an opportunity for a reform that would save the country a tidy sum each year.

Canadian engineers have not yet tackled this problem with the vigour that is one of their natural characteristics. It is principally a problem for the civil engineer; but the miner is involved as 'the one who can best supply the proper rock. Fortunately, good trap rock or its equivalent is fairly well distributed throughout the east and west of Canada; the prairies have a road problem all their own. It is not good enough for the engineer to say that the financial authority who controls his expenditure will not give him the additional fifty cents or dollar per yard required for good rock; he must insist upon good material here as he would if he were building a bridge.

The present shoddy road surfaces are a reflection on the judgment and ability of Canadian engineers. It is up to them to institute a reform.

### CANADA'S RAILWAY PROGRESS

One of the outstanding features in Canada's development and one that has much to do with the progress of other lines of industry is that of the railways. The growth of railways has been almost phenomenal, especially during certain periods, and while, due to known causes, eras of depression have been encountered, on the whole the operation of Canada's railway lines has been remarkable.

The expansion of settlement, the rapid progress of agriculture, the development of mineral and forest industries, says the Natural Resources Intelligence Ser-

vice of the Department of the Interior, have called for the construction of many miles of railway, both of trunk and branch lines, and announcement is made by both the Canadian National, Canadian Pacific and the Ontario systems that several additional branch lines and extensions are under construction or in contemplation for the present season.

Commencing with 1871, the first census period following Confederation, when Canada had but 2,695 miles of railway, with an invested capital of \$257,035,188, Canadian railways made steady progress until 1911. At that time 25,400 miles were in operation, with a capital investment of \$1,528,689,201. In the five-year period between 1911 and 1916, however, railway expansion was almost phenomenal, 1916 showing 37,434 miles in operation, an increase of 12,034 miles in the five years, and capital of \$1,893,125,774. This heavy programme of railway construction was deemed necessary to meet the needs of the country, and so it has developed. Slower progress is reported since 1916 as during the war period practically no building took place. The year 1921, however, shows railway mileage in Canada as 39,841, with capital investment of \$2,164,687,636. The total earnings of the railways in 1916 were \$261,888,654, and expenses \$180,542,259, while for 1921 the earnings were \$458,008,891, and expenses \$422,581,205.

Nothing probably could give a better indication of Canada's industrial growth than railway traffic, both passenger and freight. In 1901 steam railways carried 18,385,722 passengers, in 1911 they carried 37,097,718 passengers, while in 1920 the number carried was 51,318,422. Freight traffic shows even a greater growth, 36,999,371 tons being moved in 1901, 78,884,282 tons in 1911, and 127,429,154 tons in 1920.

The part that the development of natural resources is taking in providing freight traffic to the railways is evident in the fact that in 1901 the tonnage of forest products was 5,301,519, in 1911 it was 13,238,347, and in 1920 22,278,880 tons was handled. Grain provided 4,694,853 tons of freight in 1901, 7,545,516 tons in 1911, and 14,295,458 tons in 1920. Products of mines in 1911 supplied the railways with 28,652,236 tons of freight and in 1920 with 45,075,968 tons. Manufactures, into which natural resources enter almost universally provided 13,573,347 tons of freight in 1911 and 32,925,394 tons in 1920, among the latter being wood pulp and paper with 3,447,614 tons.

To handle this traffic the railways used 2,433 locomotives in 1901 and 6,030 in 1920; 1,159 first-class passenger cars in 1901, and 2,212 in 1920; 45,904 box and cattle cars in 1901 and 167,128 in 1920; 23,123 coal and flat cars in 1901 and 45,188 in 1920.

The expansion of agriculture, the development of forest, mineral and fisheries resources, with their concomitant manufacturing activity portend for the Canadian railways a period of increasing freight traffic and the resultant expansion necessary to keep pace with the demands for the moving of this rapidly growing tonnage.

## MINER AND CHEMICAL MANUFACTURER

The publication recently by the Dominion Bureau of statistics of its summary report on "Chemical and Allied Products in Canada, 1921" directs attention to the close alliance between the chemical and mining industries. Their community of interest is well illustrated in the following instances, among numerous others.

Our principal mineral product is coal, which provides at present in other countries, and eventually will provide in Canada, one of the principal raw materials for the chemist's use. The manufacture of coal tar products has been barely commenced in this country, and its possibilities are vast. The proposed establishment of plants to make coke for domestic use may mark the occasion of a serious attempt to build up a coal-tar industry. We have the coal, the chemists and the opportunity, but still lack the capital and the business enterprise required.

The fertilizer industry is not growing with the rapidity it should. Unfortunately, we have no adequate deposits of phosphate at present discovered; but nitrates are available in abundance from our coal provided we adopt the means necessary to save it. Here, again, the use of coke as domestic fuel will solve the problem. Potash we have likewise in abundance, but locked away securely in our deposits of feldspar, with no key at present to open them for use. The provision of soluble potash from feldspar is a favourite field for research, and at any time a commercial process may become available.

Our paint industry is in the hands of capable and energetic leaders, and even through the period of depression it declined but little. A large part of the paint industry is dependent directly upon minerals products, viz: iron oxides, lead and zinc, with titanium oxide as a possible important addition to the list. The miner and the paint manufacturer have, most distinctly, a common interest.

Only artificial abrasives are listed for 1921. Since 1921 the mining of garnet has commenced, near Bancroft, Ontario. It is used to make red sandpaper and for other special uses and provides a restricted but remunerative market. The manufacture in the electric furnace of artificial abrasives has virtually superseded the mining of the corresponding natural varieties, so that we must look to our cheap hydro-electric power to expand this important industry in Canada.

The miner and the industrial chemist have decidedly a common interest. The miner furnishes a large and growing part of the raw materials the chemist uses in his factories. It will pay both of them to establish a closer *liaison* than that existing at present, that the chemist may know more about the raw materials available, to adapt his processes to their use, and that the miner and prospector may prosecute their search for valuable minerals with a better knowledge of what is required.

The sudden and unexpected strike of coal miners at Sydney Mines last week was settled as quickly when the British Empire Steel Corporation re-instated the nine men at Florence colliery whose dismissal caused the strike. The company's action may be interpreted by the miners as a sign of weakness, but we prefer to consider it an evidence of the spirit of toleration, which is much more characteristic of the company's attitude than it is of the Bolshevik-led miners. The fact that the miners' executive called out the maintenance men, in violation of the rules of their central organization as well as of the dictates of justice and common sense, demonstrates once more the extremely dangerous frame of mind their "red" leaders have engendered. The present event seems to be a direct and deliberate defiance of the general headquarters of the United Mineworkers of America, whose delegates recently have been investigating District Number 26.

## RESEARCH

### A Symposial Trilogy

#### Vox Populi:—

Say, these here bugs and microbes that  
Them college fellers hunts,—  
I sez it now, and always, — flat —  
I've no use for them stunts!  
I'd sooner die the good old way,  
The way our fathers done,  
Than put up any of my pay  
To give the doctors fun.  
And this here talk about research  
It sure gives me a pain:  
Them guys should get right off the perch.  
I says, once and again,  
It's me, and workers like me, what  
Produces all the wealth;  
We pay for all them fellers' got,—  
And all We have is health.

#### Bourgeoisie:—

Research is an excellent thing, I admire it;  
But I'm not at all sure that conditions require it.  
I hardly see where just exactly to fit it,  
Although it is needed,—I frankly admit it.

#### Intelligentia:—

A sheer and frank commercialism marks  
The spirit of the times. No heav'n-born sparks  
Are sighted in the firmament of thought,  
No message from the Outer Marches caught.  
And Science, heretofore a lambent flame  
Of pure abstraction, is no more an aim.  
But is applied to so-called things and men  
To utilizing dogfish, or a bean.  
The love of learning, but for learning's sake,  
Is dead within us. How then shall we make  
Our souls' communion with the earthly race  
When all the world has turned poundstake?

# Ontario's Triumvirate of Great Mining Areas

A REMARKABLE TRIANGLE

By WILFRED G. MILLER

The diagram shows the relative positions of the three great mining areas, Sudbury, Cobalt and Porcupine together with those of the other known ore centres in north-eastern Ontario. What may be called, if an astronomical term is permissible, the satellites, or should we say silver planets of Porcupine in the region, as they contain gold deposits, are Kirkland Lake, Larder Lake, Night Hawk Lake, Matachewan and West Shiningtree areas, respectively. The satellites of Cobalt are the silver producers, Gowganda and South Lorrain, together with others of minor importance in the surrounding region. While no other locality in north-eastern Ontario is of much importance compared with Sudbury as a producer of nickel-copper ores, these metals in association have been mined in small quantity in one other area and are known to occur elsewhere.

It will be noted from the diagram that the gold areas occupy the northern part of the region shown, the silver the more central and southeastern, and the nickel-copper the southern. While this broad grouping may be made, it should be added that it does not fully represent the distribution. Silver, for instance, has been found in minor quantities, and under conditions characteristic of its occurrence in the region, about 15 miles south-west of Porcupine, approximately on the side of the triangle that forms the line joining Cobalt with Porcupine. Also gold ores have been mined at no great distance to the northeast of Sudbury and also to the westward, and nickel-copper ores have been worked about 20 miles to the northeast of Porcupine. But the diagram shows the distribution of the more important known mineraliferous areas.

Leaving out of consideration post-Paleozoic erosion, the region has been subjected to at least what may be called two great periods of denudation since the gold deposits were formed and to one since the nickel-copper of Sudbury and the silver-cobalt deposits came into being. Vast thicknesses of rock have been removed from the surface and doubtless innumerable ore deposits have been destroyed. For instance, the Temiskaming series of sediments, in or near which so many important gold deposits are found, as indicated by its remnants, once occurred in great volume, but is now represented only by comparatively narrow belts and outliers of rock here and there throughout the region for a distance, north and south, of over 100 miles, and east and west, with its eastward extension into Quebec, of at least 150 miles.

That the Nipissing diabase, with which the silver-cobalt ores are genetically connected, occurred in much larger volume is evident from the fact that it is now represented here and there throughout the region by outcrops of considerable extent and by smaller outliers. Hence the present distribution, especially of the important gold and the silver-cobalt deposits, represents only what has been left after great erosion.

For some years the writer has been accustomed to speak of the "triangular" relations of Sudbury, Cobalt and Porcupine. Recently Mr. P. A. Jackson, of the

topographical staff of the Ontario Department of Mines, kindly undertook the determination of the character of the triangle, the length of its sides and the direction in which they lie, together with the size of its angles. The nature of the triangle has been determined with as great precision as is possible from existing maps, with a result that can be said to be very interesting even if it cannot be used to elucidate a scientific theory nor adapted to solve economic problems. It will be noted that the triangle possesses a right angle and that one side has a due S. W.-N. E. strike, while that of another is N. W.-S. E. Who would have thought that the architecture of any part of the earth's crust was on such exact geographical lines?

It may be added that there is no genetic relation between the gold deposits of Porcupine and the silver of Cobalt, the former belonging to an earlier period than the latter. In the case of the ores of Cobalt and Sudbury there is, however, a distinct relationship. The nickel-copper ores of Sudbury are genetically connected with norite, while those of Cobalt are connected with the Nipissing diabase. The norite and the diabase are believed to be of the same age, and in chemical composition they are practically identical. They differ only in the form in which they have crystallized.

The region as a whole, as has been shown by the writer elsewhere, presents as interesting features in the way of faults of great length and lines of weakness as are to be found anywhere. The faults are indicated by the longer diameters of lakes, the courses of rivers and other structures, some of which have been determined in mining operations. One great system has a general N. W.-S. E. strike and the other N. E.-S. W. The latter appears to be connected with the occurrence of certain ores in the region, and has been made use of in prospecting, discoveries of cobalt ores for instance having been made by testing a continuation of an in-

licated fault 15 miles or more to the S. W. of the nearest known occurrence.

The subjects of erosion, faults and the genetic relations of the Sudbury norite and Nipissing diabase, briefly described in preceding paragraphs, have been dealt with in the writer's report (4th edition) on the Cobalt area, Ontario Department of Mines, Vol. 19, part 2, 1913, as well as in earlier editions.

### ACTIVITIES AT ANKERITE

The North America Gold Corporation has commenced active work at the Ankerite Mines, Porcupine. During the last few weeks, the power plant has been overhauled and increased in capacity and unwatering of the several shafts and underground workings is now complete. Shafts Nos. 2 and 4 and the drifts from them are now dry. The more extensive workings at the 200-foot level of the central shaft were reached by the pumps last week, and the water was pumped out of the drifts at the 350-foot level during the present week. Mr. Clifford Smith, president of the Corporation, and Mr. Norman C. Stines, consulting engineer, are both on the ground preparing a plan for the full development and operation of the property.

The Ankerite property was staked in 1910, but no work of importance was done on it until Mr. Smith took it over after an examination made late in the season of 1915. Work of exploration and development was begun in the spring of 1916 and was carried on actively under Mr. Smith's direction until 1918 when operations were suspended until now. With the exception of the Dome Mines development, this was the first serious exploration work done in the great shear-zone of Porcupine that extends south-westward from the Dome, across the south-east part of Tisdale and north-west of Deloro townships.

The demonstration of the occurrence of important ore-bodies at the Ankerite aroused much local interest, and considerable curiosity and speculation resulted from a sudden suspension of operations in 1918. No authoritative reasons for cessation of the work were given out, but it is now generally understood that differences of policy arose between the parties interested at that time and that the suspension of operations had no relation to the merit of the property.

The North America Gold Corporation acquired titles to the property in August, 1922, but operations were delayed further until this company succeeded, in January last, in cancelling certain underwriting contracts that it claimed had been violated by unauthorized advertisements of stock last October. These advertisements were immediately suppressed at the time by officials of the Corporation, on the grounds that they were issued without authority and in distinct violation of contract by optionees of a certain block of stock, which was a part of the treasury stock set aside for the Ankerite financing. After cancellation of these underwriting contracts was formally completed, the Corporation entered into a new agreement with substantial private capital and the proposed development and operation of the Ankerite is now fully financed. The enterprise is a private one and no stock will be offered to the public. It is understood that the interests that have now come into the North America Corporation are among the most prominent in the mining world. Quiet investments like this by strong min-

ing capital are coming into the Northern Ontario gold-fields now to an extent that is not appreciated yet by the general public.

The Porcupine Paymaster property, which has produced such spectacular ore in development during the last few months, adjoins and carries extensions of several of the veins in the Ankerite vein-system No. 2, and the United Mineral Lands Co., owned by the Boston interests in control of the Paymaster, are now developing extensions of the Ankerite vein-system No. 1 eastward. Development of this section of the Porcupine field by adequate capital will be watched now with renewed interest.

### A NEW MAP FOR PROSPECTORS

The Geological Survey, Ottawa, has now ready for distribution three new maps. Publication 1965, a map to accompany a memoir by W. A. Johnston, shows the geology of the Fraser Delta (Vancouver and vicinity) on a scale of a mile to the inch. Publication 1978, a map on a scale of 250 feet to the inch, shows the Flinflon ore-body, and will accompany F. J. Alcock's report in Summary Report, Part E, 1922.

Map 155A, should be in the possession of all those interested in the mineral industry of Northern Ontario. It shows, on a scale of 8 miles to the inch, the geology, so far as known, from the north shore of Lake Huron to the Transcontinental Railway, and from the eastern side of the new Duparquet and Opasatika map-sheets in Quebec to the western part of the Michipicoten district. All available sources of official information have been used in the compilation of this map, and the geology has been compiled and correlated by the Director of the Survey, Dr. W. H. Collins.

Though the larger part of this area of over 50,000 square miles is still shown white on the map, indicating that it has not yet been surveyed geologically, still the principal geological features are either determined or indicated. Thus the areas of Keewatin rocks, which are of prime interest to prospectors, are either mapped entire or are indicated where they cross travel routes that have been surveyed. Large areas of granite rock, within which the chances of finding ore-deposits of economic importance are very slim, are delineated, and the labours of the geologist in tramping across these barren rocks will serve as a warning to prospectors to keep away.

There is no doubt that some of the correlation involved in the geological legend of this map will be a fruitful source of discussion among students of geology; but meantime it will prove a most useful guide to those whose impulse sends them exploring, either in person or by proxy.

### VALUE OF PANNING

Panning is the prospector's method in searching for placer gold; it is an art requiring practice. Although the particles of gold are hammered so thin in their passage downwards that it may take one or two thousand of them to make the value of one cent, each of these "colors" may be easily visible. So a good long "tail," making a brilliant show, might be worth only one twentieth or one fiftieth of a cent. But when the prospector gets skill in estimating the value of the tail, panning becomes his best helper in hunting for gold in veins and placers.

# MINING IN THE KOOTENAYS

Mining and Smelting Operations Already well Established. Wide Scope for Further Development

By A. G. LANGLEY

One of the features of "British Columbia Day" at the Northwest Mining Convention was an address by A. G. Langley, resident Mining Engineer with headquarters at Revelstoke, on the mineral resources and the future mining prospects of the eastern section of the Province. He gave a description of present conditions, sketched the geology, and made interesting reference to the mining history of one of the most productive mineral regions of the Canadian West, as follows:

The district commonly known as the Kootenays comprises some 35,000 square miles of mountain territory to the north of the international boundary line, which separates it from the States of Idaho, Montana and Washington.

To the east it extends to the divide of the Rocky Mountains, which forms the boundary between British Columbia and Alberta. On the north it reaches to the end of the Selkirk range, round which the Columbia makes a big bend and pursues its course in a southerly direction. On the west it is bounded by the divide of the Gold range, which rises from the westerly shores of the Arrow Lakes.

## Production

The Kootenay country has the distinction of being the oldest lode mining district in British Columbia, and it is not very old at that, for the first discoveries, with few exceptions, of silver-lead ores only date back to the early "nineties." Ever since these discoveries were made in the Slokan and elsewhere, the district has been responsible for the bulk of the Canadian production of lead and zinc. Today it occupies a more important position among the world producers of these metals than ever before in its history.

Last year the silver production was estimated at 2,165,266 ounces, the lead at 67 1-2 million pounds, and the zinc at slightly over 57 million pounds. As far as I can gather, the greatest prospecting activity took place before the days of the Klondike boom, which was responsible for the exodus of a lot of our best miners and prospectors. If it had not been for this, it is probable that the country would have been more thoroughly prospected and a greater number of properties opened up and brought to the producing stage. However, there have been a number of very important discoveries since these early days, among which might be mentioned, the "Standard" in 1911, and the "Florence" about 1914. The fact that promising new finds are continually being made goes to show that the district has great potentialities and is in reality still in its infancy as a mineral producer.

## Recorders and Resident Mining Engineer

The district is separated into twelve mining divisions, namely; Revelstoke, Trout Lake, Lardeau, Ainsworth, Slokan, Slokan City, Arrow Lakes, Nelson, and Trail Creek in the West Kootenay, and Golden, Windermere, and Fort Steele in the East Kootenay. In each of these divisions there is a mining recorder, at whose office much information may be obtained relative to the location and ownership of properties. The office of the Resident Mining Engineer is at Revelstoke. Here various reports, geological maps and other data are available to those who wish information regarding the district and the various mining properties. Advice is freely given, when possible, as to the best methods of development of prospects, to those who are not familiar with conditions in this part of

the country, and everything is done to help, in any way possible, legitimate mining enterprises.

## Transportation

Although a rugged, mountainous country, the greater part of it can be travelled without much difficulty or hardship as it is well opened up with excellent trails, while the C. P. R. lake and rail service provides good transportation facilities to the smelter from the most accessible and active parts of the district. In some of the outlying areas where little mining activity is going on, the problem of transportation is, and has been, a severe handicap; but this is being rapidly overcome by motor haulage, and wherever ore in quantity has been developed the Government is always willing to grant substantial assistance towards defraying the expense of road construction, under a special Act named the "Mines Development Act."

## Smelting Facilities

The immense and up-to-date smelting plant of the Consolidated Mining and Smelting Company at Trail accepts for treatment the ores of copper, gold and silver-lead-zinc. It was only last year that this plant was equipped with a customs zinc plant. This alone has been a great help to the miners of silver-lead-zinc ores, for previously great difficulty was experienced in getting rid of their zinc ore and concentrates, which often carry high values in silver.

## General Geology

A summing-up of the general geology will probably help those who are not familiar with the district to grasp the main features. On the east, the Rocky Mountains, forming a great barrier between British Columbia and the prairies, were uplifted during the close of the Cretaceous period. They owe their origin to an immense thrust from the direction of the Pacific; igneous activity has not been responsible for their upheaval. They are composed of beds of limestone, sandstone, shale and quartzite. A section along the line of the Canadian Pacific Railway from Golden to the prairies presents nearly every geological period. No important ore-bodies have as yet been developed in these mountains, with the exception of the "Monarch," at Field, which has produced a considerable tonnage of lead zinc ore. However, the Cretaceous measures in the Crow's Nest area include immense quantities of coal. A good deal of prospecting has been done for oil in the Flathead Valley, which area was reported on by the late J. D. MacKenzie of the Geological Survey.

There appears to be rather more evidence of mineralization in the southerly portion of these mountains near Fort Steele, where prospecting has been carried on for a number of years, while Wild Horse Creek has yielded a large amount of placer gold.

Coming westward from the Rockies and crossing the Columbia river, we enter the Purcell and Selkirk ranges, which occupy the central part of the district and in which the great majority of our Kootenay mines are located. These mountains were formed during the Jurassic period by an immense intrusion of granite, which has folded and contorted the overlying sediments. In places the granite is laid bare by erosion, in others it is covered by thousands of feet of stratified rocks. Near the contact with the granite the sedimentary rocks have been intruded by dykes, stocks, and sills originating from the main batholithic mass. In these zones of marginal contact many of our

most important ore-bodies have been discovered, both in the igneous rocks and in the sedimentaries.

### Local Geology of the Camps

In the Slocan the ore-bodies occur in sheared fissures in the Carboniferous slates and limestones of the Slocan Series, in close proximity to porphyritic dykes and occasionally in the porphyry.

The Rossland ore-bodies are associated with basic igneous rocks. The great deposit of silver-lead-zinc ore of the Sullivan mine is a replacement deposit in argillaceous quartzites. Its mode of occurrence and the character of its ore are said to be similar to certain deposits in the Coeur d'Alenes. I am not aware of any igneous rock having been encountered in the mine workings, but the deposit occurs in an area that has been intruded by the gabbros locally known as the Purcell sills. Unlike the main range of the Selkirks, the Purcell mountain area is mostly underlain by sediments of pre-Cambrian age.

In both the East and West Kootenays the mineralized zones following the trend of the Purcells and Selkirks can be traced from near the international boundary far into the undeveloped and practically unexplored areas in the northern extremities of the district.

### The Ores of the District

The predominant ores of the district are silver-lead-zinc, although gold ores have been mined extensively and are distributed over a vast area. Rossland in past years has been the main source of gold, not only for this district but for the whole of British Columbia. The camp has been rather quiet for the last year or so, but big things are expected when the large concentrator at Trail will be available for the low-grade ore of this camp. According to reports, the Consolidated Mining and Smelting Co., will have this plant in readiness shortly after their new concentrator at Kimberley is completed.

Quartz-filled fissures in schists, quartzites and granite are the most common type of gold deposits found throughout the district. Outside of Rossland, the Nelson division has been the largest producer of gold in this district; in it are the famous camps of Ymir and Sheep Creek. Here again we find that many of the deposits are in close proximity to intrusive igneous rocks. Placer gold exists in a number of localities, notably Big Bend and Wild Horse creeks, where work is being carried on at the present time.

Rossland has also been the chief source of production of copper. There are a number of copper prospects throughout the district, some of which give promise of substantial production; but so far little development has been done. The most promising areas for prospecting would appear to be in the Fort Steele and Revelstoke mining divisions.

There are known deposits of hematite, arsenopyrite, magnetite, barium, molybdenum, antimony, gypsum, asbestos and chromium, which may have commercial values but at present are not being mined.

### Mining Conditions Favourable

Generally speaking, the natural conditions of the Kootenays lend themselves to mining. There is usually a abundant supply of timber available for mining purposes and sufficient water-power for milling and mining operations. In most cases the ore-bodies can be attacked by adit tunnels, thus eliminating the expense of pumping and hoisting. The climate is healthful and invigorating. I would judge that the average elevation of the mines is about 5,000 feet, while that of the valley floors ranges from about 1,500 feet to 3,000 feet above sea level.

I believe there has never been a more favorable time than the present for mining silver-lead-zinc ores in the

history of this district, except perhaps during a short period of abnormal conditions produced by the war. Metal prices are good and smelting rates favorable, and for the first time in the history of British Columbia, zinc ore and concentrate are acceptable to the Trail smelter. The shipper receives payment for the zinc and silver values contained, providing the value of the latter is sufficient to pay for smelting the residue from leaching. This has had a far-reaching effect throughout the district, and has greatly stimulated the mining of zincky ores, which heretofore were looked upon in many cases as a liability rather than an asset.

### Abandoned Properties now Producing

During recent years a remarkable feature of the Slocan, which has great significance in connection with future developments, has been the result obtained by opening up and developing abandoned properties. For instance the "Queen Bess," after lying idle for a number of years, was re-opened by Clarence Cunningham in 1916, with the result that an ore-body was developed that yielded something like \$1,000,000 clear profit. Further development at the "Wonderful" has disclosed the vein in place, and the big mill at Alamo is now running on ore from this property. The "Ruth" is another property that has been lying idle for a number of years. In 1921 it was re-opened by leasers, who soon uncovered a good showing of high-grade lead ore. Last year the property was acquired by a Vancouver syndicate and development has been steadily proceeded with. The results obtained have been highly satisfactory and it is probable the property will soon become an important producer. The "Slocan Star" is not quite in the class of abandoned properties, but ore was becoming scarce and prospects did not look bright just before the big ore-shoot was discovered on the 1,000 foot level in 1918. It is now a regular payer, and the leading producer of the Slocan. There are many other instances, not only in the Slocan, but elsewhere in the district, of the value of many of the abandoned mines.

### New Metallurgy Aids Old Properties

In considering the possibilities offered by some of the old abandoned properties, we must visualize the conditions that existed during the earlier history of the camps, and must appreciate the following facts: The improvement in ore concentration due to oil flotation allows a much better recovery of the silver values and cleaner lead and zinc products. Dry silver ores, carrying values in grey copper and argentite and possibly other silver sulphides, were not amenable to concentration before the introduction of the oil flotation process. Now it is possible to make a good recovery of the silver values in such ores. Lastly, and possibly most important of all, we have now a more intimate knowledge of the geology and character of the deposits; hence development work can be conducted with greater intelligence. So today it is possible to work properties at a greater margin of profit than formerly, and in some cases the present-day economies were not possible in the earlier days. A great deal of Spokane capital has been invested in the Slocan and Ainsworth divisions; but I would like to point out that undoubtedly there are opportunities in other parts of the district, for the rocks of the Slocan series traverse the Trout Lake and Lardeau divisions and can be traced far north of the main line of the C. P. R. into the Big Bend district. There are a number of properties in this zone that are well worthy of careful investigation, and I fully expect to see more activity in this part of the district during the next few years.

### East Kootenay Mines

In the East Kootenay the bulk of the tonnage of silver-lead-zinc ore has been produced by a small group of prop-

erties in the Cranbrook area, namely, the "St. Eugene" at Mervin, the "North Star" and "Sullivan." Of these the "Sullivan" is the only property being actively worked at present. It is probably the largest deposit of lead zinc ore on the continent, if not the world, while the "St. Eugene" and "North Star" have both produced large tonnage. In the northern part of the East Kootenay, mining activities are mostly centered in the Windermere district, where the "Paradise" mine has been an important producer for a number of years. The predominant ores in this area are also silver-lead-zinc and occur in limestone and argillite. It is extraordinary that in a distance of 60 miles between the Windermere camp and the "Sullivan," no silver-lead ore deposits of any great commercial value have so far been discovered. The same applies to the stretch of country between the "Sullivan" and the "St. Eugene," a distance of about 30 miles.

In the Windermere country there are a number of promising prospects, and the same applies to the Golden area to the north.

The East Kootenay mountain area comprises a vast expanse of country which, it is safe to say, has not yet been thoroughly prospected, and for all we know there are other deposits just as important as the "Sullivan" and "St. Eugene" lying hidden on the slopes of these mountains.

### ENGLISH MINING CAPITAL IN CANADA

The Anglo-French Exploration Company of London, which has invested substantial sums in Canadian mining companies during recent years, held its annual meeting last month. Canadian mining securities now take a prominent place in the Company's assets. The chairman mentioned that "the company has, for the last 33 years, terminating 31st December, 1922, been enabled to distribute out of its liquid resources in dividends, interest or return of Preference capital something like £2,097,600, besides which the company has never gone through any reconstruction or writing-off of capital."

The company's securities in the Rand mines were reduced during the year, and it was noticed that their Australian and Canadian interests improved, while oil holdings in Trinidad were very successful. Of Canada, the chairman said:

As regards Canada, which presents a likely field for our operations, a good deal of attention has been drawn to Canada during the last few months. The phenomenal success of the Hollinger mine and the recent developments at the Keeley mine and at the Premier have been much in evidence of late. We have been represented for the last 12 years by Mr. J. B. Tyrrell, whose knowledge of this vast territory is probably unequalled, and whose qualifications as a geologist and mining engineer are well known. You will perhaps remember that some six years ago, Mr. Tyrrell attended our annual meeting and spoke to us about Canada. I should like to quote the following paragraph from a paper read by him in December last before the American Association for the Advancement of Science. He said:—

"At the present time our country offers a field for extensive and intensive research second to none in the world. One of the main objects of that research should be the finding of bodies of ore which could be economically developed and utilized for the benefit of mankind. There is no finer laboratory anywhere than the one in which this research must be conducted, for it was constructed by the Great Architect of the Universe Himself; it is almost limitless in size, in variety of problems to be solved, and in the facilities for solving them."

"I think no better description could be given than this. There is no doubt that enormous mineral wealth lies buried in Canada's 3,750,000 square miles, which is an area equal to the whole of Europe, including Russia. Its very vastness is, however, one of its difficulties, and it must be remembered that for half the year it is under thick snow, when very little prospecting can be done. As illustrating the vastness of Canada, I may mention that the distance between the two principal mining centres—namely, those in Ontario and in British Columbia—is much the same as between London and New York.

"Most of the mineral deposits of Canada have, I believe, been discovered by accident; for example, it has been stated that the placer gold mines of the Klondike were discovered in 1896 by an Indian woman as she was going to draw water from a well; but in any case it was an accidental discovery made by untrained people. As a result of this accidental discovery, the Klondike produced millions of pounds' worth of gold. A somewhat similar thing occurred in connection with the nickel mines near Sudbury and the rich silver mines at Cobalt, which were discovered by men working on the railways, while what is now the Hollinger mine, in Porcupine, one of the greatest gold mines in the world, was traversed for a century or more by traders before the gold-bearing veins were discovered some 13 or 14 years ago. To-day the country is being prospected in all directions, and the prospector has not to depend solely upon his luck, as he has the records and assistance of the Geological Survey of Canada and of the Geological and Mining Bureaux of the various provinces to direct his steps to places where the geological formation is favourable to the occurrence of ore bodies. Under these conditions it will not be surprising if this great country is forced to disclose its hidden treasures, and that we may see a great advance in the development of the mineral resources of the country. We are fully alive to these possibilities; we are watching the position very closely, and you may depend upon it that we shall be well informed as to any new discoveries or developments.

"Our Canadian business has so far shown us a profit and we are at present in one or two promising ventures. We have the organization to deal with any fresh business which may come forward, and should the prospects justify it we are prepared to strengthen our organization to deal with it."

### MINERALS OF SOUTHWEST AFRICA

The mines of the Southwest Africa Protectorate are described in a recent number of the *South African Engineering and Mining Journal*. Only the merest fringes of its 400,000 square miles has been explored for minerals, and its geological features make it unusually attractive to prospectors. During the German occupation some mines were opened up, and some of these are being operated. The most prominent mineral deposits are the diamond diggings near Kolmankop, which were discovered in 1908. The diamonds occur in alluvial deposits along and near the seacoast, in an arid region. In 1919, before the slump in the diamond market, the output of the various properties was 462,000 karats of a value of £1,500,000. At Trumeb in the Grootfontein district there are important high-grade deposits of mixed copper and lead ore. This is partly smelted on the spot and partly exported in the raw state through the port of Wallvis Bay. A smaller copper deposit, provided with a 50-ton concentrator but not now being worked, is the Khan mine, in the southeastern part of the Protectorate. Tin ore in small amounts is being produced from placers in the Erongo mountains. No coal has been found in the Protectorate.

## JOSEPH KEELE---AN APPRECIATION

By WYATT MALCOLM, Geological Survey of Canada.

In the death of Joseph Keele on June 11, 1923, Canada lost a most faithful and efficient public servant. As Mr. Keele was not accustomed to announce the results of his work with a blare of trumpets, his contributions to the development of Canada's resources were not fully appreciated by the general public. But those who were most thoroughly conversant with his work and most competent to judge of its merits appraised it at high value.

Mr. Keele was born at Parsonstown (Birr), Kings county, Ireland, on December 24, 1863. He came to Canada at an early age and spent his youthful days in Peterborough and vicinity. He graduated with honours from the School of Practical Science, Toronto, in 1893 and the following year took the degree of B. Sc. with honours at the University of Toronto. From 1894 to 1898 he served on the staff of the School of Practical Science. One cannot imagine his service in this connection as anything but highly satisfactory. The thoroughness with which he planned his work, the precision with which he carried it out, and the convincing though quiet tone and unostentatious manner in which he expressed himself were qualities that fitted him eminently for the task.

His first employment with the Geological Survey was as assistant to the late Dr. A. E. Barlow in his well-known investigations in the pre-Cambrian geology of Hastings county. His appointment to the permanent staff of the Survey was made in December, 1901.

In his earlier independent work he carried on geological explorations in Yukon and Northwest Territory. One of his most important exploratory trips consisted in ascending Pelly and Ross rivers in Yukon, crossing Mackenzie mountains, and descending Gravel river to its junction with the Mackenzie in 1907 and 1908, a trip that necessitated his wintering in the mountains, and that meant hardship and a severe test of physical endurance. Of such matters, however, Keele was extremely reticent; his modesty permitted him to speak but little of personal matters and his sense of duty well done was his best and most gratifying reward. Readiness, on the other hand, to recognize merit in others is illustrated by the following tribute to his assistants on this exploration: "It is impossible to speak too highly of the services rendered by these two men; suffice it to say here that owing to their skill, energy and foresight, an expedition, which in less capable hands was liable to be attended by disaster at any stage, was carried through in safety and comparative comfort."

He was an enthusiastic student of glacial geology and when the Geological Survey decided to institute investigations into the clay and shale deposits of the country and their application in the ceramic industries, there was probably no member of the staff better qualified by temperament and training to undertake this work than Keele. The work was initiated under the direction of Dr. Heinrich Ries of Cornell University. After some time spent in co-operation with Dr. Reis in the field and in the laboratory of Cornell University, Keele continued the investigations independently.

In his work on the clays and shales he discovered

himself. Few individuals have ever fitted with finer adjustment into their chosen callings. He was seldom happier than when testing the raw materials used in the clay products industries, advising the practical man on methods of procedure for obtaining the best commercial results, or testing the artistic effects of some new kind of glaze. It is for his work in clays and shales that he is best known, and it was in this work that he made his most valuable contribution to the industrial progress of his country. His training as a geologist enabled him to see his subject from a different angle from that of the pure technologist, and to derive great pleasure from its pursuit. He was especially interested in the growth of industries for the manufacture of the better grades of clay products, and aimed at the development of a type of artistic pottery distinctively Canadian in material, form and decoration. It is to a great extent through his efforts along this line that the teaching of pottery was introduced into some of the public schools of Canada.

An interesting thing in connection with his clay investigations was his discovery in eastern Canada of pre-Glacial sediments that are believed to be of Cretaceous age.

Mr. Keele was transferred to the Mines Branch of the Department of Mines in 1916, where he continued his investigations in ceramics. In 1921 he was promoted to the position of Geologist in the Geological Survey of Canada, a position which he held until his death. He was a member of the Canadian Institute of Mining and Metallurgy and of the American Ceramic Society.

During the winter of 1922-23 he made a trip to the Mediterranean, ascended the Nile, and visited the tomb of the ancient Egyptian king Tutankhamen. The previous winter he visited Australia and New Zealand. These trips were full of enjoyment, as Keele was a keen student of geography and of the relationship of man to his physical environment. Moreover, he had a sharp eye for what other countries and civilizations, ancient or modern, had to teach regarding ceramics.

He will be remembered by many Ottawans as one who in a quiet pleasing manner related the story of his trip up the Nile, and painted vivid pictures of modern Egypt and its past greatness. By his colleagues he will be remembered as a friend, unobtrusive and free from self-seeking, who sat and chatted in a cool, collected manner, with clear reason and sound judgment, about interesting geological problems or questions pertaining to the welfare of the institution with which he was connected, ending frequently with a half humorous, half cynical remark about the frailties or foibles of humankind.

He had an acute sense of duty, and we can well believe that it was through no spirit of adventure but rather through a feeling of obligation to the country of his adoption that he was led to don the soldier's uniform at the time of the Northwest rebellion.

He was intensely loyal to his country and to the Government department of which he was a member; and was at all times actuated by what in his judgment conduced to the best interests of both.

# BOOK REVIEW

## EL ARTE DE LOS METALES (METALLURGY)

Translated from the Spanish of Alonzo Barba, by Ross E. Douglass and E. P. Mathewson. Published by John Wiley & Sons, Inc., 432 Fourth Avenue, New York. 276 pages.

It speaks well for the translators of this priceless relic of another age, and equally well for the publishers, that they were moved to enrich our literature with a gem that would otherwise be lost to all those of us unfortunate enough to be unable to read Spanish.

Alvaro Alonzo Barba, Master of Arts, was Curate of the Parish of San Bernardo, Potosi, Bolivia. His work, the earliest extant on American metallurgy, was originally presented as a report to the Deputy of the Crown in the year 1637. It was approved and recommended to the Crown for publication by the Deputies of the Royal Village of Potosi and the Amalgamators' Guild. It was first printed in Spain in the year 1640, and reprinted twice thereafter, in 1675 and in 1729. Numerous translations into German and French appeared within the succeeding century. Only one very inadequate English translation, that of the Earl of Sandwich, appeared. The noble earl, who was Ambassador Extraordinary to Spain, did half of the book into our language in 1669, but failed signally in his attempt to interpret the technical terminology of the volume. The present translation was made from the Madrid Edition of 1729, the text of which was carefully compared with that of the first edition (1640) copies of which are preserved in the British Museum. Tradition has it that the first edition was banned by the Inquisition.

The volume is divided into five books entitled, respectively:—

- (1) The Manner in which Ores are Begotten, and the Things that accompany Them.
- (2) Amalgamating Gold and Silver Ores.
- (3) Treatment of the Ores of Gold and Silver by Cooking (Pan Amalgamation).
- (4) The Reduction of all Classes of Ore by Smelting.
- (5) Refining and Parting Metals.

Barba's geology, of course, was tinctured with the fantastic speculative thought of his times. But his attempt to simplify and co-ordinate the mass is wholly praiseworthy. For instance, in discussing the genesis of stones, he writes thus:—"Stones have their varying forms which distinguish them into different species. Ignorant of the conditions, we define them by indefinite terms based on their outward appearance and irregularities. The form of each one is accompanied by its special virtues, which are much greater than those in plants and animals, being in proportion to the greater length of time occupied by nature in their generation." The workings of a truly philosophic mind may be seen here. Again, in discussing the creation of metals, he writes:—"If dryness predominate in the mixture, stone results; and if it has a greater amount of greasy water in it, metal results...and thus they flow and melt under the action of heat...Many of the generality of people, in order to avoid profound discussion, say that in the beginning of the world God created ores in the form in which they today exist and are found in their veins. This is an offence to nature, denying to her, without any reason, the productive virtue she possesses in all sublunar things. Furthermore,

"experience in many parts of the world has proved to the contrary." This last sentence is naïvely indicative of Barba's real value.

In Chapter 19 of the First Book, Barba defends the opinion of those who claim that mercury and sulphur are the essential components of metals. "It is of no importance", says he "that they try to show that metals are not composed of sulphur and mercury by saying that these substances are not present in their mines; for these, as component parts, acquire a different nature from that in which they were created, and abandon their primitive form." There is no controverting this kind of argument, and so, we suppose, Barba's opponents were squelched.

When Barba begins to treat of practical matters, the details of metallurgy, he is much more at home. Homilies against the errors of ignorance are interspersed throughout. The volume concludes thus:—"Most rare in the World is it to find persons who have obtained some advantage from their knowledge of the art."

A word as to the translation. Messrs. Douglass and Mathewson have done their work with more than scholarship. They have shown sympathetic understanding and discriminating skill. The result is that we have not, what any student of Spanish could give us, a mere transliteration; but we do have a vital translation in which the idiomata of the original are preserved and in which the beauty and dignity of Barba's language are not lost. Indeed, the achievement of the translators is something of which all mining men may well be proud. It could have been done only by ardent and informed lovers of good books.

J. C. MURRAY.

## KNIGHT CENTRAL'S FINAL MEETING

The Knight Central's last annual meeting of shareholders was held last month, and the chairman's statement contained an interesting summary record of the mine's history. It is one of the smaller of the Rand's mines, for during the 28 years of operation it has crushed but 4,230,000 tons of ore, from which was won gold to a value of £4,970,000. Working capital paid in was £847,000, and the total of dividends, £112,500. When the assets have been realized, the shareholders will have received only half their original subscription, during a period of over a quarter of a century. Extensive exploration of the reef within the Company's ground has failed to disclose payable ore. The financial record of the average Rand mine has, of course, been much more satisfactory than this.

## FOLLOW THE FLOAT

Discoveries of lead ore in the Gaspé Peninsula have been made by finding pieces of float galena, sometimes weathered to a rounded brownish mass, and trenching uphill from these finds. The vein-out-crops usually show only white or brownish quartz, from which the zinc blende and most, if not all, of the galena have been weathered out, leaving the quartz in a cellular condition. Where galena has been left in the quartz, it may have a reddish brown coating.

The French occupation of the Ruhr industrial area has stimulated the chemical industry of the United States by means of cutting off the supply of low-priced chemicals from Germany, which results in an enhanced price for American manufacturers.

# Natural Gas and Petroleum Resources of Western Canada

II. — Progress of Exploration in Sweetgrass District

By NEWTON W. EMMENS\*

The total crude oil in storage in the United States increased during the month of April by 5,889,000 barrels (U. S.) to a total of 263,915,000 barrels, according to the figures of the United States Geological Survey, and operators in the big producing fields are getting together with a view to stopping all unnecessary drilling, and cutting down the output of oil from existing wells with a view to stabilizing the price of crude oil and preventing the further declines that are sure to come if production is maintained at a level so far in excess of the demand.

## The Montana Oil Field

Meantime, drilling in the Kevin-Sunburst field of Toole County, Montana, continues in the proved oil producing area, with some wildcatting to the north, east and west. In this field there are 57 producing oil wells and 8 gas wells. There are 46 wells being drilled, with 37 locations additional that have been authorized. There have been 19 dry holes drilled in the field thus far. The oil production of the individual wells is not spectacular, in spite of some newspaper statements to the contrary, being from 20 to 80 barrels when pumping is resorted to.

## Promising Well on the Alberta Side

On the Alberta side, in the Sweetgrass district, the Imperial Oil Company's test in Sec. 5, Tp. 1, R. 16 W. of 4th Mer. has reached a depth of 2,542 feet. At 2,525 feet a showing of light oil was encountered in what is believed to be the Kootenai sand and some oil was brought up with the bailer. On deepening the hole in the hope of increasing production, water was encountered. Consequently it was considered advisable to set a packer and shut off the water so that the oil-producing part of the sand may be thoroughly tested. This is now being done. This oil showing is the best yet found in the Sweetgrass area on the Alberta side. No oil, gas or water were found in this test-hole above the 2,525-foot level. Several other wells are being drilled in this locality and it is probable that an oil field of commercial importance will be developed on the Canadian side of the border.

## The Central Alberta Fields

Important developments are expected during the present summer from the central Alberta fields, where the Imperial Oil Company and British Petroleums are carrying out a comprehensive development programme following the successful drilling of test wells in the Irma-Fabyan-Wainwright sections. While no commercial oil pool has thus far been developed, it is a fact that every well drilled to the Lower Cretaceous strata has found oil; but it is the variety to which the name "maltha" has been given, being the heavy residue left after the more volatile portions of the original crude oil have been driven off. It is the opinion of the writer that a careful and systematic search will result in the discovery of commercial oil pools in central

Alberta, where the rocks have been subjected to less metamorphism than is the case in the Irma-Fabyan-Wainwright field and that the guide to such a discovery lies in the study of the carbon ratio of the coal or coaly deposits that occur in the strata overlying those containing petroleum (both liquid and gaseous). In addition to the "maltha" found in the wells as above referred to, large flows of natural gas have been found. This gas is now being tested and experiments are being carried on with a view to its profitable use.

## PETROLEUM IN ENGLAND

It is not commonly realized that England has an oil well whose annual production exceeds that of the average well in the United States. It is near Hardstoft in Derbyshire. The Duke of Devonshire has lately acquired a concession of approximately five square miles in that vicinity for the purpose of sinking further wells. It is possible that a considerable quantity of oil will yet be found in England, as exploration for it has barely been commenced.

## CANADA'S OIL REFINERIES

With the exception of the United States, Canada ranks as the greatest user of automobiles in the world, on the basis of population. The amount of fuel which these motor vehicles annually consume reaches millions of gallons, and to supply this enormous demand a very extensive and lucrative industry has been built up in Canada. According to the Dominion Bureau of Statistics, there were in operation in Canada in 1918, 10 petroleum refineries, three of which are located in Ontario; three in Alberta; and one in each of the provinces of Nova Scotia, Quebec, Saskatchewan and British Columbia.

Capital invested in these various refineries during the fiscal year 1918 amounted to \$35,745,410, of which \$23,535,257 represented land, buildings, fixtures, machinery and tools. Bills receivable, cash, trading and operating accounts amounted to \$407,408, while materials on hand, stocks in process, finished products, fuel and miscellaneous supplies on hand were valued at \$11,802,745. The cost of fuel used in the refineries was \$3,242,796, of which sum, oil and gasoline used represented \$1,721,642; 247,423 tons of bituminous coal worth \$1,425,850; and the balance, or \$95,304, for petroleum, coke and natural gas.

According to reports 262,641,149 gallons of crude oil were received at the refineries, of which quantity 12,258,184 gallons were from Canadian wells and 250,382,965 gallons imported. The total cost of oil received at the works was \$23,708,659, of which \$22,789,762 was paid for imported oil and \$918,896 for the product of Canadian wells. Petroleum and petroleum products imported were valued at \$13,127,178, of which \$13,359,616 was paid for 229,010,561 gallons of crude oil imported by oil refineries to be refined at their own plants.

\* Petroleum Engineer, Vancouver, B.C.

### Wage Earners and Wages

The average number of wage earners engaged in these industries was 2,968, and the wages paid allowed a per capita payment of \$1.15 or a total sum of \$3,413.92. Wages paid to 272 salaried employees amounted to \$71,676, or an average of \$1,366 each. The total wage and salaried employees was 3,240, while wages paid totalled \$4,874,318.

The selling value of the subsidiaries of the total production was \$17,800,907. Of this sum \$19,247,402, or 50.8 per cent., was the value of 72,169,916 gallons of gasoline and motor oils; \$7,130,301, or 18.8 per cent., the value of 56,220,066 gallons of illuminating oils, and \$6,629,980, or 17.50 per cent., of 84,784,278 gallons of fuel and gas oil and tar.

Practically all the products of the refineries were consumed at home, a small quantity, however, being exported. Crude coal oil or kerosene exported in 1918 amounted to 370,309 gallons valued at \$28,415, and of refined oil 1,946,967 gallons, valued at \$206,675. There was also an export of naphtha or gasoline of 91,229 gallons valued at \$28,788. — "Agricultural and Industrial Progress in Canada."

### PERSONAL AND GENERAL

Dr. H. Foster Bain, director of the Bureau of Mines, has been deputed to visit Chile for the purpose of securing an authoritative estimate of the tonnage of nitrate available there. Such an estimate is desirable to aid the Government authorities in arriving at a logical and commercially sound policy for the manufacture of synthetic nitrates in the United States.

Mr. H. S. Denny, who has paid a professional visit to the Kirkland Lake gold camp, will visit some properties in the gold-silver camp north of Stewart, B. C., to which the Premier Mine has drawn world-wide attention, before he returns to London.

Mr. D. H. MacDougall, who held conferences with the representatives of the Cape Breton steel workers last week, is to confer with the directors of the British Empire Steel Corporation in Montreal this week relative to the steel workers' requests.

Hon. Robert Drummond, of Stellarton, Nova Scotia, continues to be the active public proponent of the coal and steel industries of his province. In a recent issue of the *Financial Post* he explained how the unduly high cost of coal in Nova Scotia cripples a steel industry that should be one of the most important in the world.

Dr. Leopold Reinecke, well known in Canada as a former member of the Geological Survey, is now in consulting practice in Johannesburg, South Africa.

Mr. H. S. Munroe, General Manager of the Granby company, was in Allenby last week, inspecting the Copper Mountain mine and concentrator. He was accompanied by Colonel Crabbe, President of the company.

Mr. J. B. Haffner has been appointed General Superintendent for the Granby company at Aiyon.

It is estimated that the value of the silver-lead ore now being shipped from Mayo, Yukon Territory, will be \$1,250,000, and that the season's gold output will be over \$1,500,000, the highest total for years past.

Nickel-chromium alloys, while resistant to a great many kinds of corrosive liquids and gases, have been found by experiment to be attacked by sulphurous gases.

### EXPLOSIVES SAFE WITH CAREFUL USE

Investigations conducted by the United States Bureau of Mines relative to the hazards involved in the handling of explosive materials indicate that the number of accidents in handling and testing explosives is relatively low; in fact, it is lower than in some supposedly less dangerous occupations. Workers who handle explosives, being aware of the danger, practise carefulness until it becomes a habit; in consequence accidents are relatively few. Accidents from explosives, however, receive more publicity than do most industrial accidents.

Any feeling of nervousness by a man engaged in handling explosives is highly dangerous, as it may result in his dropping a batch of sensitive material or knocking over a piece of apparatus. Men subject to nervousness should overcome it or get out of the industry. All explosives should be treated with proper respect, but it is not necessary to feel that the slightest jar will be disastrous.

The Bureau of Mines estimates that at least 75 per cent. of all the industrial accidents with explosives are caused by hurrying the work and by taking chances where conditions are known to be dangerous; probably 20 per cent. are due to carelessness, the rest having at least fairly excusable causes. The great essential in avoiding accidents is that inexperienced men should be made fully conscious of every movement in handling explosives and should be trained to "play safe" until they are automatically careful all the time. Nearly all men become accustomed to working with explosives and feel no nervous strain, although after a bad explosion only a person of unimaginative temperament can work without excessive nerve fatigue.

In the laboratory a chemist naturally avoids spattering or spilling materials on his clothes or skin, or inhaling the fumes or fine particles of any explosive. Benzene, toluene, aniline, and their nitro compounds, besides other compounds, are known to be poisonous, but so is hydrogen sulphide, which all chemists use.

When preparing samples of explosives many analysts wear rubber gloves, but the usual course is to see that the hands are dry, to avoid direct contact as much as possible, and to wash the hands as soon as the sampling is finished. When possible, it is best to bathe the hands in a dilute solution of sodium sulphite, which acts as a solvent and is not readily absorbed by the skin.

### RADIO STATION FOR DAWSON

Last week the Federal Government voted \$55,000 for the establishment of radio stations at McMurray at the end of the steel in northern Alberta, Fort Simpson on the MacKenzie River, and Dawson in the Yukon, which will displace the telegraph lines at present in use from McMurray northward and into Dawson. The sum voted for the construction of these radio stations is \$55,000, while a sum ranging from \$275,000 to \$300,000 has been voted annually for the last twenty-three years for the telegraph services.

### ASBESTOS ROOFING IN INDIA

The Canadian trade commissioner in India reports that there is at present a good demand for asbestos roofing of good quality from the railways and public works departments. Iron roofing is of comparatively short duration in the climate of India, and asbestos roofing has proved to be eminently suitable for use in these tropical conditions.

# CANADIAN VICKERS

Plant Now Adapted to General Industrial Construction

Canadian Vickers, like the parent firm in England, began its career as a ship-building establishment, based principally upon the express intention of our Federal Government of ten to fifteen years ago to build up a Canadian navy, composed of vessels built in Canada. A very substantial plant was put down in Montreal and a corps of highly-trained engineers and mechanics gathered, principally from England, to man the works. The plant did notable service during the war time, not only in the building of small naval craft, merchant ships, marine boilers and engines and ship accessories, but in the manufacture of shells as well.

The after-war conditions have necessitated a radical change in the plans of Canadian Vickers. Their large floating dock and the dry-dock will always be a necessary part of the port of Montreal's facilities for ship repairs; but the possibilities for ship-building are reduced to special craft such as dredges and tugs. Consequently the firm has had to extend its activities in other lines.

## Present Industrial Activities

General industrial construction now constitutes an important part of Canadian Vickers' work. The machinery and equipment used for ship-building is especially suitable to handle heavy industrial construction, while the shops designed to make marine engines and accessory marine machinery can handle a very wide range of construction, both heavy and light. A sep-

arate draughting office has been equipped for the purposes of this work and additions made to the staff to cope with it effectively, and already there has been turned out of the shops a wide variety of machinery and equipment for land use. Mine skips and cages, mine cars, ball and tube mills, crushers, elevators, and other mine and mill equipment have been turned out recently for Canadian mines, and the shops are ready to make steam and electric hoists, screening equipment, all kinds of steam boilers, heavy duty rolls, and special work for mines.

Heavy plate work can be handled with unusual facility in the powerful machinery designed for ship construction. There were recently completed some tanks made of two-inch plate, welded and rivetted, designed to withstand a test pressure of 750 pounds per square inch, for oil refinery use. Revolving asbestos dryers are also a product of this part of the shop. In addition, lighter plate work, where required to be of first rate construction, can be made economically in this department.

The engine and machine shops are still at work on marine engines and deck machinery; but their scope has been enlarged by the manufacture of the Vickers-Petters semi-Diesel oil engine.

## Aeroplanes

A new department has been opened recently that may have soon a direct bearing on the mining industry. An aeroplane department has been organized in close

Canadian Vickers' works at Maisonneuve, Montreal, showing 25,000-ton floating dry-dock, ship-building sheds, fitting-out wharf and shops. In the floating dock is an ocean liner.

Vickers Viking Amphibian, with 50-foot wing spread, accommodates pilot and five passengers. It is especially suited to Canadian conditions, as it is rugged in construction, has a wide radius of flight, and can travel on land and water as well as in the air.

co-operation with the Vickers Air Craft Works at Weybridge, England, but with a special view to Canadian conditions. Its activities were inaugurated recently on receipt of an order from the Dominion Air Board for eight Vickers Viking Amphibians which will be powered with Rolls-Royce "Eagle" engines. This represents a class of aeroplane developed since the war, and especially suited for use in Canada. It is equipped

to arise from, and alight on land or water at will, and for the landing wheels can be substituted skis, which permits uninterrupted use during the winter months. The undercarriage with wheels is drawn up beneath the boat that forms the fuselage when not required, and let down again at will by the pilot. The term "Amphibian" has thus a specific and special meaning, as the craft is literally able to travel alternatively on land or on water at will. This option has been shown by test to result in a much longer life for the Amphibian than for seaplanes or flying boats, which must be carried or hauled from the beach to their hangars, with consequent damage to their hulls and wings. The independence and complete adaptability of the new type overcomes this difficulty.

The Vickers Viking has a span of 50 feet and a length of 33½ feet. The wings can be folded to a width of 33 feet 10 inches. The standard engine equipment is a 450 horse-power Napier "Lion," and drives a pusher airscrew. The net weight is 3,728 pounds, or 5,600 pounds with fuel and load. It accommodates five passengers, or the pilot and 1,070 pounds of baggage. The normal speed in flight is 119 miles an hour, and the landing speed 50 miles per hour. The range at 6,000

3-ton mine skips made for the McIntyre Mine, Porcupine.

Special car for carrying drill steel, built recently for the Hollinger Mine.

feet elevation and at full speed is 350 miles, and at a reduced speed of 90 miles per hour, 480 miles. The climbing qualities are remarkable; the time to 6,000 feet is 7.35 minutes. The "ceiling" is at 18,250 feet.

The Vickers Viking "Amphibian" has been tried out thoroughly not only in England but here in Canada, where the Laurentide Air Service, Limited, a private company, have used it for two seasons. It is noteworthy that it was the only machine to be awarded the British Admiralty £10,000 prize for amphibian machines against numerous competitors. Thus the first of Canada's aircraft factories is now making, not only the latest and most effective post-war type of machine, but one most completely suited to Canadian conditions.

#### Vickers Agency

Besides these and other facilities for construction in Canada, Canadian Vickers are agents for the parent company in England and for the extensive association of firms connected with them. Vickers Limited own or control works throughout England manufacturing almost every sort of industrial or domestic appliance, from stainless cutlery and automobiles to heavy ordnance and gold dredges. Many of these products are not yet made in Canada, and are thus made readily available from the workshops at the centre of our Empire.

### EXPERIMENTAL BLAST FURNACE OPERATES SUCCESSFULLY

Details of an entirely successful test run of the experimental blast furnace operated by the United States Bureau of Mines at the North Central experiment station, Minneapolis, Minn., have just been received by the bureau. This test run marks the culmination of four years of experimentation by the Bureau of Mines, in co-operation with the University of Minnesota, in the development of this blast furnace, which is unique in the field of industrial research. During the entire run every phase of operation of the furnace was under complete technical control. Several tons of commercial gray iron and of spiegeleisen were made. With this demonstration of the possibility of operating an experimental blast furnace, with every detail of furnace operation under technical control, it is believed that the investigators at the Minneapolis station are now in a favorable position to undertake the study of various problems, the solution of which should be of great practical value to blast furnace operators.

After blowing in, the furnace was operated as a slagging type gas producer until it had reached a steady state thermally and chemically. A series of thermal-couples, located at five elevations in the mantle, were used to determine the travel of the heat wave up the charge column as the cold material used in filling the furnace gradually acquired heat from the ascending gases generated by combustion at the tuyere zone.

When the top temperature indicated that the furnace had reached a steady state, iron ore, without the addition of flux, was charged and its descent in the furnace was followed by means of gas samples taken from various planes up the side of the mantle. It was found that reduction began shortly after the iron ore had been charged and was completed at a point remarkably close to the stock line. The ore used in this experiment had been sized so that the particles were a little smaller than garden peas. When the effect of this charge had been dissipated, more of the same size iron ore was charged without any lime stone and another set of gas samples was taken.

The purpose of these experiments was to obtain a com-

parison of the gas composition at various planes of the furnace when no reduction was taking place and when an iron ore burden had been charged. Such a comparison indicates the levels in the furnace where reduction starts and where it is completed.

Without changing any of the operating details the physical character of the burden was changed to a less homogeneous ore size (ore particles varied from pieces about two inches in diameter to fine ore). A black slag, indicating incomplete reduction, appeared after this burden had been charged a sufficient length of time for it to pass through the furnace. The burden on the furnace was decreased and the scouring slag disappeared.

Several rounds of fine ore were next charged and the reduction at the stockline was found to be greater than when a coarser ore was used. This was indicated by higher carbon dioxide.

These examples are cited to indicate how a study was made of the effect of sizing of ore upon its reduction in the blast furnace.

An iron ore burden was charged continuously for several days, approximately three tons of gray iron being made per day. Towards the end of the run several tons of spiegeleisen were made from manganiferous iron ore from the Cuyuna Range. Gas samples were taken on this ore, as well as on the iron ore, from five elevations in the mantle during the operation.

The furnace was operated for twelve days and blown out empty and in good mechanical condition. No serious difficulty was experienced in operating the furnace. A large number of gas, slag and metal analyses are yet to be made. Likewise, a number of temperature, pressure, and other readings are to be studied.

### CHROMIZING

The metal chromium has for many years been used for making alloy steel, but its power to resist corrosion and to confer this property on other metals when alloyed with them is a comparatively recent discovery.

Mr. F. C. Kelley, in a paper read at the New York meeting of the American Electrochemical Society, May 3-5, gives the results of an investigation which had for its object the application of the well-known principle of "cementation" to chromium. The "case-hardening" of soft iron by heating it, below its melting point, in a bed of charcoal, is an old process, illustrating the power of diffusion of solids, slow indeed when compared with the rapid diffusion of gases, but nevertheless capable of industrial application. Sherardizing (with zinc) and calorizing (with aluminium) are processes in which these metals in the solid state are diffused into the surface layers of other metals so as to confer certain properties on them.

In chromizing, the object is heated in a mixture of powdered alumina and chromium, the alumina being used as a diluent and to prevent sintering. This must be done in an atmosphere free from oxygen and water vapor, either of which would oxidise the chromium at the high temperatures used.

The chromium used in this operation must be at least 95 per cent pure. It is worthy of note that the process for the manufacture of metallic chromium at a high degree of purity was developed in the metallurgical laboratory of Queen's University, Kingston, to make possible the manufacture of stellite alloys. Chromizing may therefore be considered a logical outcome of that valuable piece of research work.

Steel objects when chromized acquire a bright silvery, non-corrosive surface. By a subsequent heat-treatment, the loss of power to stand high tension and fatigue stresses may be restored to the steel.

## COBALT

The metal, cobalt, is a modern product, although its oxide has long been used to make the beautiful small blue of painters and chinaware manufacturers. In a paper presented at the New York meeting of the American Electrochemical Society, May 3-5, Dr. C. W. Danks, gives a short statement of the present position and future prospects of the cobalt industry. The annual world production of about 400 tons of cobalt compounds is not large, but it is forty times as great as it was in 1860. In addition to the metal there are now produced fifteen compounds of cobalt. The metal is used chiefly in the manufacture of stellite and as one of the main constituents of permanent magnets. The use of cobalt makes possible the manufacture of magnets of half the weight necessary when the ordinary tungsten magnet steel is used.

The oxide is used mainly for coloring in the ceramic and enamel industries, and in the manufacture of cobalt salts. These are used as driers in paints and varnishes, as catalytic agents in the hydrogenation of oils (which converts oils into solid fats), in the preparation of certain printing inks, and in stains in the ceramic industries. In enamels, cobalt is used to neutralize the yellow tinge due to iron.

Ontario provides practically the world's requirements. The strength of her position is due to the fact that cobalt and its compounds are by-products in a mining and metallurgical industry that does not depend on them. It is doubtful if the extraction of cobalt can be made to pay when, as in the West Australia ore, it is the sole product. In the Belgian Congo (Katanga) there are deposits of copper ore high in cobalt, and it was thought that these deposits might supply the demands of Europe and Asia, but the event has so far not fulfilled the hopes entertained.

In the Ontario region, the cobalt content of the ores is decreasing, and with the growing demand for cobalt and its compounds, there seems to be no danger of an oversupply, but rather the contrary.

## SOCIAL AND ECONOMIC CONDITIONS IN THE DOMINION OF CANADA.

This is the title of No. 196, Vol. 107 (May 1923) of *The Annals of the American Academy of Political and Social Science*, edited by Clyde L. King. The editor in charge of this volume is W. P. M. Kennedy, M. A., Litt. D., of the University of Toronto. The social and economic conditions of Canada are discussed by some forty-four writers, mostly well-known Canadians. Part I is devoted to *Population*, about which there are some interesting statistics, not the least so being the statements of the Quebec Provincial Statistician, that 5,800 French immigrants, the estimated number arriving between 1634 and 1759, were the parent stock of the whole French race in America, now numbering 3,500,000 souls, a population six hundred times greater than the number of original colonists. In eight short essays other writers discuss such aspects of Canadian population as growth, migration to the United States, the immigrant settler, Oriental immigration, the aboriginal races, and Canada's immigration policy.

Under Part II, *Resources and their Development*, the mineral resources of Canada are discussed by Mr. Balmer Neilly, Secretary of the Ontario Mining Association. Mr. Neilly begins by quoting from the presidential address of Dr. C. V. Corless to the Canadian Institute of Mining and Metallurgy, a passage that should have the widest possible publicity. We reproduce it here in order to compare its statements with that of the Dominion Statistician (p. 5),—

"Canada is predominantly an agricultural country." According to Dr. Corless, "We live in a country whose greatest permanent sources of wealth are its soil and its minerals. But few people, however, realize that not more than about fifteen per cent. of its entire surface is suitable for profitable cultivation. Of the two largest provinces generally considered as mainly agricultural, the proportion is probably less than ten per cent. I shall endeavor to show that the remaining eighty-five per cent contains mineral treasures of inconceivable value."

Taking this as his text, Mr. Neilly lays before the reader of *The Annals*, an imposing array of what Canada has so far accomplished in developing this field. The result can be summed up in the statement that in the thirty-five years from 1887 to 1921, the value of the annual mineral production has increased fourteen-fold. During that same period the population has not quite doubled.

In Parts III to IX there is a comprehensive survey of education, transportation, money and banking, foreign trade, public finance, Canada's rural problem, the agrarian movement, protection of workers in industry, labor problems, etc., the sustained interest being assured by writers of wide and varied experience, among whom may be mentioned, Sir Edmund Walker, John Lewis, Sir Thomas White, W. C. Good, M. P., The Hon. H. S. Beland, J. S. Woodsworth, M. P., and others equally well qualified.

## RAND GOLD PRODUCTION

Production of the Transvaal gold mines for the month of April was 743,651 fine ounces as compared with 761,586 fine ounces in March. These figures show a decrease, compared with March, of 17,935 ounces, but the daily average output was better, as April had two working days less. The value of the April gold output at par (85s per ounce) was £3,160,517, and at the declared value (87s. 6d.) £3,253,473. At the end of April the gold mines employed 178,337 natives as against a total of 181,473 at the end of March. While most of the gold mines are making very satisfactory profits and are on a dividend-paying basis, some are being operated at a loss.

## A NEW NICKEL ALLOY

"Permalloy," a nickel alloy of remarkable magnetic properties, is described by H. D. Arnold and G. W. Elmer in the May issue of the *Journal of the Franklin Institute*. Alloys of nickel and iron containing over 30 per cent nickel show these dielectric properties, but "the most startling results are obtained with an alloy containing 80 per cent nickel and 20 per cent iron, whose permeabilities at small field strength are many times greater than any hitherto known." A revolutionary change in submarine cable construction and operation, as well as other fields of usefulness, is predicted as a result of the discovery of the new alloy.

## FIRES AT MINTO MINES

Legal proceedings have been instituted as a result of fires at Minto, New Brunswick, where a shaft-house and some freight cars were burned in a fire suspected to be of incendiary origin. There had been previously some disaffection among the coal miners employed on the property.

The present ore reserves of the Geduld Proprietary, South Africa, consist of 3,800,000 tons, assaying 8.1 dwts. and 2,500,000 tons, assaying 4.5 dwts. The latter amount is now included in the reserves by virtue of the decreased mining costs following the strike of last year.

# THE MINING DISTRICTS

BY THE JOURNAL'S CORRESPONDENTS

## NORTHERN ONTARIO

**Mineral Production.**—The report of the Department of Mines covering the production of the metalliferous mines, smelters and refineries of the Province for the quarter ending March 31st, shows an encouraging increase, although there is a decrease in both gold and silver. There has been a substantial increase in the output of nickel and copper, due to the renewed operations of the International Nickel Company. Metallic cobalt, cobalt oxide, nickel oxide and nickel-cobalt compounds show large increases, and have an aggregate value of \$1,927,000, as compared with \$355,000 for the same quarter in 1922. Silver, valued at \$1,793,000, shows a decrease of slightly over \$200,000. The Gowganda area did not show any shipments, while South Lorrain was an important producer with 826,775 ounces, Keeley 530,000, Mining Corporation (in Cobalt) 311,000 ounces, and in South Lorrain 297,000 ounces, Coniagas 268,000 ounces. The production of gold amounted to \$4,374,000, a decrease of \$300,000 as compared with the same quarter in 1922. When the severe power shortage however at the mines is taken into consideration, it might have been expected that the decrease would have been much more than this. The Hollinger shows the largest decrease, which amounted to almost 30 per cent. This falling off was due, in a small measure, to the lower grade ore treated, but was almost entirely due to the lack of power. The average grade treated by the Hollinger was \$7.61 per ton, as compared with \$11.12 for the McIntyre and \$12.81 for the Dome. Although the Dome tonnage decreased, the higher heads accounted for the production being about the same. There was a substantial increase in the output of the Kirkland Lake district, which was largely due to the Teck-Hughes. The average recovery of the ore treated by that mine for the quarter was \$29.42, which is the highest in the history of the mine, and is also the highest for the Kirkland Lake district. The average recovery of the Lake Shore was \$22.74, Wright Hargraves \$9.04, Kirkland Lake \$4.80 and Kirkland Lake Proprietary \$6.64.

**Nipissing Production in May.**—The report of the Nipissing Mining Company for May shows that the company mined ore of an estimated net value of \$187,241 and shipped bullion of an estimated net value of \$170,000. The value of the silver was estimated at 65¼ cents an ounce. The production of cobalt amounted to 31,845 pounds. The low-grade mill treated 7,161 tons and the high-grade plant 188 tons. The refinery shipped 253,566 fine ounces of bullion. The company has declared the regular quarterly dividend of 3 per cent, payable July 20th to shareholders of record June 30th. The financial statement as of June 2nd shows cash, investments, value of ore and bullion on hand, in process and in transit amounting to \$4,676,000.

**Mining Corporation in April.**—The report of the Mining Corporation for April shows that the company treated 4,645 tons and recovered 48,050 ounces of silver. The cost of the mine operations amounted to \$34,575. The production from the Company's Cobalt mines was reduced owing to an experimental run of 1200 tons of Peterson Lake ore. During the month the production from the South Lorrain properties amounted to 183,500 ounces.

**Keeley Report.**—The quarterly report of the Keeley Mines, for the three months ending March 31st, shows that there was recovered 423,368 ounces from 6,577 tons of mill ore and 36 tons of hand-picked ore. The gross value of the product was \$278,326.00, from which the estimated profit was \$188,900. Expenditure on capital account, which was not taken into operating expenses, was \$28,817. The ore reserves as of March 31st were estimated at 1,728,000 ounces of silver, with the addition of 1,250,000 ounces if the No. 26 vein goes up 30 feet and carries the same values as in the drift. Developments during the quarter were exceptionally good, particularly on the 7th level. 75 feet of work on No. 26 vein produced 250,000 ounces of silver.

**Colonial Makes First Shipment.**—The Colonial has commenced shipping some mill ore to the Mining Corporation mill. Underground developments have not yet progressed to the point where a regular tonnage can be counted upon, but indications are promising.

**Kirkland.**—The Montreal-Ontario has started a crosscut on the 300-foot level to intersect the two veins cut on the 250-foot level. It is understood that the crosscut showed values up to \$20.00.

An official report from the Kirkland Lake Proprietary has stated that crosscutting has been started on the 800-foot level. The new vein recently found on the fourth level has been developed for a distance of 67 feet and averaged \$6.75 over 57 inches.

The Kirkland Gateway proposes to commence diamond-drilling in order to locate at some depth the extension of the veins found on the surface. Drilling will be done from the 350-foot level.

The shaft of the Harvey-Kirkland is down about 300 feet and will be continued to 400 feet before lateral work is undertaken.

John Taylor & Sons have let a contract for sinking the Queen Lebel shaft to 300 feet. Some encouraging values were found on the surface.

**Larder Lake.**—On the 500-foot level of the Associated Gold Fields the results are the best yet encountered, and the present face shows an average of \$10.00 over a width of 15 feet.

**Porcupine.**—The officials of the Goldale company state that while an informal proposal has been made regarding the amalgamating of the Goldale, Plenaum and Armstrong-Booth properties, no definite steps have been taken and no negotiations of an official nature have been entered into.

The Hayden Mines are cutting a station at the 700-foot level of the shaft, and when this is completed the shaft will be continued to 1,000 feet.

**The Dome Meeting.**—The Directors of the Dome headed off the expected opposition at the Annual Meeting by holding a directors' meeting before the shareholders' meeting and declaring a dividend of \$1.00 a share, payable in July. This is at the rate of \$4.00 a share a year, and is double the amount of the dividend previously paid. The President stated that the vicissitudes of mining would prevent any guarantee as to its continuance, but stated that it would be paid as long as the profits warranted it. The meeting, however, was far from being as harmonious as one might gather from

The propositions and some very pointed criticisms, particularly with regard to the financing of the company, were made. The proposal, however, to separate the local office of the company from the office of the President was voted down. The old board of directors was re-elected with Mr. T. W. Fitts of Rochester, replacing Mr. Frederick G. Corning of New York. The President stated the old scheme of capital re-payment had been abandoned, on account of a change in the United States tax laws which made it possible to tax these returns of capital. In addition there was a very considerable expense in connection with every capital re-payment. With regard to the proposed By-law permitting the formation of a new company with the shares of the old, the directors were authorized to proceed with the formation of this company and the basis on which the shares would be split was left to their discretion. It was pointed out that the present shares of \$9 par did not suit the London market and that stock selling at less than \$10.00 a share was not accepted as collateral in New York. For this reason the proposed exchange of four shares for one share of the old was not considered advisable at the present time, and it might be found advisable to issue two for one at the present time, with the possibility that later on a further split might be made. A most interesting part of the meeting, from the viewpoint of the shareholders, was the statement of the President regarding the possibilities below the 12th level. The annual report pointed to the possibility of the hanging-wall ore-bodies being cut off below the 12th level by an intrusion of porphyry, and this was a disturbing factor with many of the shareholders. The manager pointed out that an almost identical occurrence had been found in 1917 on the 8th level, and that some of the best ore-bodies had been found below that point and above the 12th level. The Dome has, however, now entered the same formation as the other producing mines of the camp, and there appears to be no reason why the ore-bodies may not be found below the porphyry intrusion. The President states that important ore-bodies have been found in the Dome Extension ground, and it was intimated that the company intended to expend \$750,000 on a new deep-level shaft in the Dome Extension ground.

### NORTHWESTERN ONTARIO

**Cross Nickel Property.**—The Julian G. Cross nickel properties, situated on Lower Shebandowan Lake, have been under option to Duluth interests for some time. Extensive surface operations in the way of pits, trenches and stripping have been carried on, disclosing a large deposit of well mineralized ground having a length of one and one-half miles.

Diamond-drilling was commenced last week, for the purpose of determining the depth of the deposit, together with the values carried below surface, the results of which will be looked forward to with interest, as the surface operations give promise of this property developing into one of exceptional value, owing to the variety and nature of the metals in the ore.

Thorough sampling of the surface openings shew that it carries an average, throughout its entire length of one and one-half miles as exposed on the surface, of 2 per cent. copper, 3 p.c. nickel, and some platinum, and also, in places, a notable amount of vanadium.

The property is about 60 miles north-west of Port Arthur, on the Canadian National Railway, immediately south of Lower Shebandowan Lake, and is easily accessible.

Should the diamond-drilling disclose similar values at depth as have been found on the surface, these properties will form the basis of an active mining community, as there is ample capital behind the operators to carry on mining work on a scale adequate to any requirements.

### NOVA SCOTIA

**Steady Shipment of Coal.**—Since June began, coal shipments have been very heavy, and notwithstanding the fact that International Pier, Sydney, is equipped for rapid loading, there were times when a number of large vessels lay in the harbour awaiting their turn. All collieries are now working full time, and operations on the coal heaps are on double shift, with steam shovels going night and day. The output from these two sources runs from 22,000 to 24,000 tons per day of twenty-four hours. At this rate of delivery, the markets of the Nova Scotia collieries should be well supplied before the season is over, that is, provided there is no cessation of employment through labor disputes or other causes.

**Two Collieries Re-opened.**—The coal industry of Nova Scotia is enjoying a season of prosperity, and all indications point to a greater spread of the trade. No. 7 Colliery, Sydney Mines, which was idle all winter, is again producing.

No. 15 Colliery had been closed down for several years, but was re-opened and repaired and is being put into condition to add to the Cape Breton output. This is one of four collieries, equipped for a daily output of 1,200 tons each. It will take some time to get the mine started, and the maximum output will be reached only in the course of a year or so. However, this mine will give employment to close on 500 men, and will make New Waterford a prosperous town.

**New Colliery on Lingan Seam.**—In this same district a new mine will be shortly opened up. Whether the location will be near one of the old mines or nearer Sydney Harbour, is not yet known. At any rate, it has been decided to open up the Lingan seam in some part of the New Waterford district, and it matters little what part so long as the seam is developed.

**Gardiner Seam to be Worked at No. 1 Colliery.**—No. 1 Colliery, one of the most profitable the Dominion Coal Company ever operated, is to be sunk to the Gardiner seam. This seam is five feet thick, and has a hard sandstone roof. The coal is clean, and of good quality, and miners, who many years ago worked it in what is known as the Gardiner Mine, say it is an ideal seam for longwall. This is yet to be proved, for no attempt was made in the early days to try out this system. Hard roof is not always the best in working the longwall system. A soapstone roof, which is tender, has often been found far more suitable than one that is too strong.

**Coal Mining Machines Under Test.**—The Dominion Coal Company are making a thorough test of coal-mining machines, and are using different machines in different collieries. The latest machine, now being tried out, is the Sullivan chain machine, electrically operated. It is giving splendid satisfaction. Two new Mavor Coulson mining machines have just arrived from Britain, and are also to be tried out. The Goodman mining machine from the United States is also among the importations, and will be tested shortly.

With the longwall method of mining in operation in one colliery, where the conveyor for loading coal is used, some progress has been made towards the European methods of mining. When the many different types of coal-cutting machines now on the ground are put into operation, the knowledge gained will be most helpful, and before long the machines most suitable to each particular seam will be in use there.

**Wages of Steel Workers.**—Sydney steel workers have been pressing their case for higher wage rates for some time, and they are still insistent that their request be granted. This time, however, they have acted with more wisdom, and are satisfied to let their claims go before the meeting of the Directors, which is to be held shortly. A policy of this sort appeals to reasonable men, and is much more likely to be successful than when mob tactics are used and threats of dire destruction are made. It is hoped that the Company will be able to meet the demands of the workmen sufficiently to show them that they are ready to do what they can to help them, when their case is presented in a sane manner. The cost of living in Sydney is high, and there is much sympathy with the working classes; but at the same time, workmen who take unfair methods of enforcing their demands lose both the sympathy and support of the public, and it is in the interest of all working men to have the good wishes of all classes of the population.

### BRITISH COLUMBIA

**Bush Mines to be Re-opened.** — The Forty-Nine and Bush mines, Salmon River, Portland Canal, are reported to have been acquired by English interests with the result that work will be resumed on the Bush. G. L. Thompson has been examining the Forty-Nine. He was for a time connected with the Hirst-Chichagof Mine on Chichagof Island.

**Gold Prospects in Omineca.** — The Peace River Mining and Milling Co., has under development a large group of free milling low grade gold properties situated on Mount Selwyn, about three miles below the junction of the Parsnip and Findlay rivers in the Omineca district. Systematic sampling of the exposures took place last season and this year machinery and supplies are to be taken in to permit the carrying on of development. It is understood that the company proposes to test 200 tons of the ore, and, if this is satisfactory, preparations will be made for large-scale operations.

**Cariboo.** — J. D. Galloway, resident mining engineer for the northeastern part of British Columbia has returned from the Cedar Creek district of the Cariboo. He says that gold is being shipped by several operators, and that new and promising placer ground has been staked a few miles from the Cedar Creek discovery. The Murray-McGregor Mining Co. has been organized to take over the discovery claims in the field lately found. James Murray is reported to have recovered on May 8th last a seven and one-half ounce nugget, while the yield, by means of rockers, has been as high as \$50 a day. The installation of modern equipment is proposed.

**Kaslo.** — The Rambler-Cariboo Mines, situated near Kaslo, is expected to resume work shortly. A. F. McClaine is the managing director.

**Ainsworth.**—The Lake Shore Mining Co. Ltd., E. J. Edwards, manager, Ainsworth district, held their annual meeting recently, officers being elected as follows: President, T. A. Preston, Spokane; vice-president, Dr. H. H. Keeler, Spokane; secretary, Walter E. Hogan; treasurer, Geo. E. Stout, Spokane; managing director, E. J. Edwards; directors, L. P. Turner, Spokane; Ed. Bates, Worcester, Mass.; and John C. Calvert, Pawtucket, R. I. The annual report showed that a 750-foot tunnel had been driven and cross cuts, although 60 feet in ore, have not yet reached the hanging wall. The results are considered satisfactory and a meeting is to be held at Spokane to consider the driving of a lower tunnel at the lake level and the installation of a mill of 150 ton daily capacity.

**Trail Ore Receipts.** — During the last ten days of the month of May, 11,386 tons of ore were received at the Trail Smelter. The Lightning Peak Mine, Arrow Lakes district, sent a small shipment and the Sidney Leasing Co., Idaho, contributed 58 tons. The details follow:

| Mine                                      | Tonnage |
|-------------------------------------------|---------|
| Alamo, Alamo . . . . .                    | 52      |
| Bell, Beaverdell . . . . .                | 36      |
| Company Mines . . . . .                   | 10,135  |
| Henderson Group, Smithers . . . . .       | 21      |
| Knob Hill, Republic Wm. . . . .           | 161     |
| Lightning Peak, Edgewood . . . . .        | 3       |
| Lone Pine, Republic Wm. . . . .           | 385     |
| Molly Hughes, New Denver . . . . .        | 10      |
| Quilp, Republic Wm. . . . .               | 206     |
| Roseberry, Surprise, New Denver . . . . . | 43      |
| Sidney Leasing Co., Idaho . . . . .       | 58      |
| Silversmith, Sandon . . . . .             | 297     |

11,386

**New Shippers Expected.** — The Cork Province Mine Ainsworth, expects to be shipping in June. The Florence Silver Mining Co. Ltd., Ainsworth, which has uncovered new ore-bodies, is preparing for operations on a considerable scale. Eighty-six men now are employed and a twelve-mile power line is to be built from Queen's Bay to the property. This will connect with the extension being constructed by the city of Nelson and will eliminate the past power problems of the Company.

**Copper Concentrate from Tidewater Mill.** — The Tidewater Copper Co., Sidney Inlet, Vancouver Island, has overcome power difficulties, caused by intermittent water shortage, by the installation of a 300 h.p. Diesel engine. Two hundred tons of ore are being mined per day, from which there is a recovery of some 12,000 lbs. copper together with some gold and silver. At twenty-day intervals the Company ships 4,000 tons of concentrate to the Tacoma smelter.

**Field Work in Northern, B C.** — Dr. George Hanson, Canadian Geological Survey, will spend the summer season in the field at Kitsungalum Valley and the northern British Columbia region from the town of Terrace to Alice Arm. He will map the Coast Range batholith in the area, will investigate the coal and mineral resources generally, and will give special attention to the reported arsenic deposits of the Hazelton District.

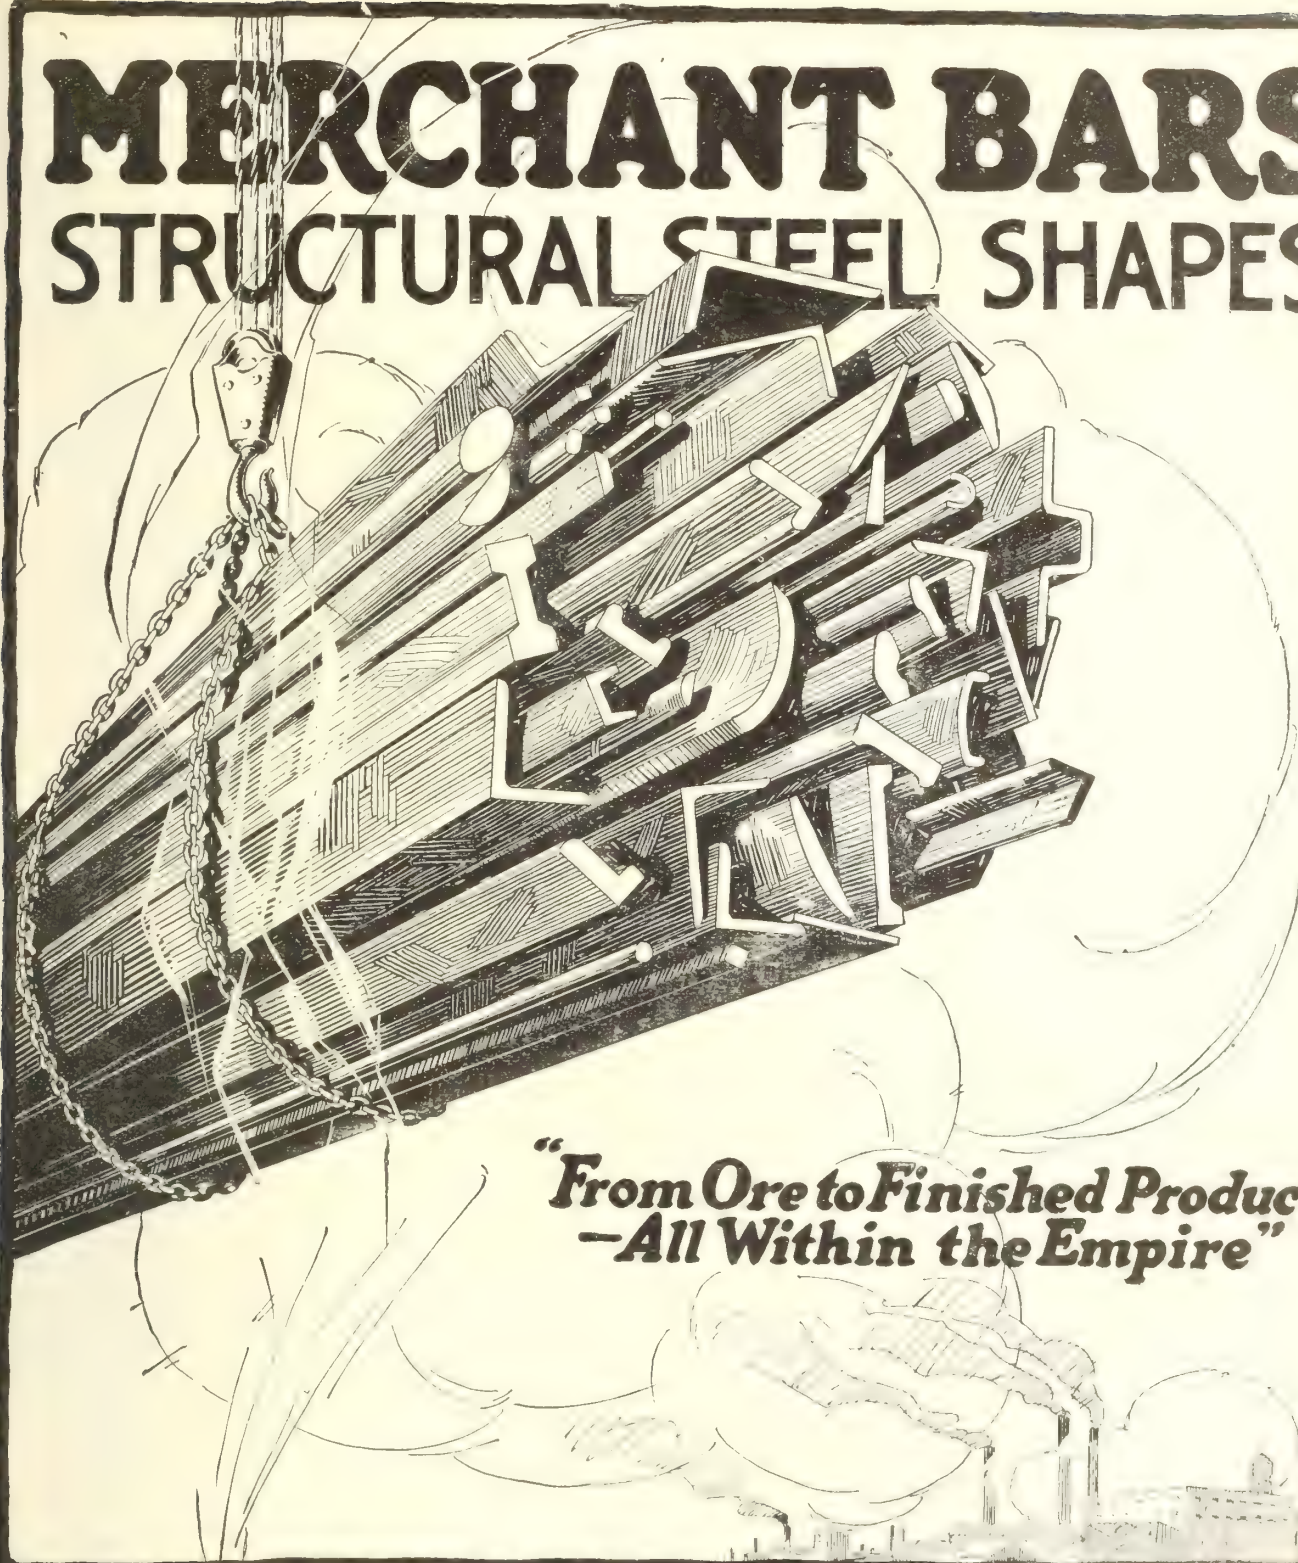

**Geological Survey of Hong Kong Island.** — Dean R. W. Brock, of the University of British Columbia, announces that the Geological Department of the Uni-

Branch Offices: 26 Albermarle St., London W., Eng.

- Summary Report of the Mines Branch, 1920.  
The Mines Branch maintains the following laboratories in which investigations are made with a view to assisting in the development of the general mining industry of Canada:
- Fuel Testing Laboratory.**—Testing value of Canadian fuels for steam raising and production of power gas; analyses, and other chemical and physical examinations of solid, liquid and gaseous fuels are also made.
- Ore-Dressing Laboratory.**—Testing of Canadian ores and minerals, to ascertain most economical methods of treatment.
- Chemical Laboratory.**—Analysing and assaying of all mineral substances and their manufactured products. Copies of schedules of fees, which are slightly in excess of those charged by private practitioners, may be had on application.
- Ceramic Laboratory.**—Equipment is such that complete physical tests on clays and shales of the Dominion can be made, to determine their value from an economic standpoint.
- Structural Materials Laboratory.**—Experimental work on sands, cements and limes is also undertaken.
- Applications for reports and particulars relative to having investigations made in the several laboratories** should be addressed to **The Director, Mines Branch, Department of Mines, Ottawa.**
- Summary Report.** The annual Summary Report of the Geological Survey is now printed in parts. Applicants should, therefore, state what particular geologist's report is required, or what subject they are interested in.

- Applicants for publications not listed above should mention the precise area concerning which information is desired.
- The Geological Survey will, under certain limitations, give information and advice upon subjects relating to general and economic geology. Mineral and rock specimens, when accompanied by definite statements of localities, will be examined and their nature reported upon.
- Communications should be addressed to **The Director, Geological Survey, Ottawa.**

## Eliminate Hot, Dusty Working Faces

In driving entries or working thin veins and pockets, the main ventilating system seldom serves the out-of-the-way places.

The air at remote working faces is usually hot, humid and dusty. Production is slow and costs high.

Canadian Sirocco Ventilating Sets, used with canvas tubing and moved from place to place as required, will bring fresh air to these troublesome spots. No matter how hot and dusty, or how far removed from the main shaft or tunnels, they can be ventilated and cleared of smoke, gases and dust, by means of these auxiliary ventilating units.

Write for bulletins showing how you can remove the dangers of dust and gases and lower production costs.

The contributing factors in making good Wire Rope are:

Men who know how  
The best grade of materials  
The most Modern Machinery

We have all 3 and are producing the goods. Give us a trial.

Our Wire Rope Catalogue is an invaluable reference book and contains many helpful ideas on the care of wire ropes and cables as well as information on the best kind of rope to use on all classes of work. A copy sent upon request.

Our other lines of Manufacture are Wire Cloth for all uses, Perforated Metals, Wire Pulp Mats, Clothes Lockers, Machinery and Window Guards, Pulp Mats, inquiries solicited.

### Absolute Uniformity In Hercules Oils

Have you had difficulty in finding a flotation oil which conforms exactly to your specifications in every shipment?

Hercules Pine Oils will solve your problems. They are produced under strict chemical control. Uniformity in every lot we send to a customer is the aim of our organization.

We would welcome an opportunity to demonstrate to you the exactness with which we can comply with specifications. We invite correspondence and offer the experience of our technical service men to help you solve any of your flotation problems.

## TORONTO MINING TANKS

Tanks used for the Cyaniding Process must retain heavy and precious liquids at pressures as high as 80 lbs. to the cubic foot and hence great care is exercised in designing and manufacturing **TORONTO Mining Tanks**. Testimonials in our files prove beyond a doubt that **TORONTO Mining Tanks** render long, satisfactory service under severe conditions.

**TORONTO Mining Tanks** are made from the finest of Air Dried Tank Stocks obtainable — air dried to give them longer life. We can supply them for Agitator and thickening processes, in B. C. Fir, Redwood, Gulf Red Cypress or Pine. Our Engineering Dept. will assist you in designing any special tanks you may require — no obligation. Our Tank booklet free upon receipt.

# Check Up the Essentials of the Ideal Re-crusher "Telsmith" possesses them all

**STRUCTURE** — As secondary crushing is very difficult work, a sturdy structure is the first and fundamental requirement. Note the very short, heavily metalled frame of the Telsmith Reduction Crusher.

**BEARING** — For the same reasons, the bearings should be ample in area, lubricated and thoroughly protected. The eccentric of the Telsmith Reduction Crusher is almost as long as the crusher itself, with a diameter to correspond. Lubrication is by oil under pressure.

**FEED AREA** — The feed openings should be ample to permit gravity flow of rock into the crusher without hand or mechanical regulation. Telsmith will work just as well under a 20-foot head of rock as with the bowl barely full.

**FLY-WHEEL EFFECT** — Discharge should be by gravity, since centrifugal discharge involves a danger-

ous accumulation of fly-wheel effect and serious wear on vital parts of the machine. Telsmith discharges by gravity through a three-arm bottom spider. The only heavy parts in rotation are the eccentric, gears and driving pulley.

**CRUSHING SURFACES** — Wearing surfaces should be ample without any concentration of abrasive action. Telsmith has an enormous crushing head and concave bowl, with wear uniformly distributed by the "creep" of the head.

**DISCHARGE OPENING** — The discharge circle must be big enough in diameter to compensate for reduced width of the opening. In the Telsmith Reduction Crusher the mean discharge diameter is approximately  $1\frac{1}{2}$  times the mean feed diameter, allowing free escape of the crushed rock even when set for the smallest product.

# Ontario's

# Minerals

PROVINCE OF ONTARIO

DEPARTMENT OF MINES

Hon. H. MILLS, Minister of Mines

## Mineral Areas.

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favorable for the occurrence of minerals, 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver mines of Cobalt occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

## Economic Minerals.

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario:—actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluor-spar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, Portland cement, brick and tile, meet every demand.

## Mineral Production.

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1921 to be worth \$48,128,387, of which the metallic production was \$27,574,202.

The following figures show the rapid growth of Ontario's mineral industry by five-year periods since 1891:

| Year.          | Value.      | Year.          | Value.       |
|----------------|-------------|----------------|--------------|
| 1891 . . . . . | \$4,705,672 | 1906 . . . . . | \$22,388,383 |
| 1896 . . . . . | 5,235,003   | 1911 . . . . . | 41,976,797   |
| 1901 . . . . . | 11,831,086  | 1916 . . . . . | 65,303,822   |

## Dividends.

Dividends and bonuses paid to the end of 1921 amounted to \$23,140,734 for gold mining companies, and \$84,388,185 for silver mining companies or a total of \$107,528,919.

## Mining Regulations.

A miner's license costs \$5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of \$2.50 or \$3.00 per acre, depending on location in unsurveyed or surveyed territory.

## Assay Office.

The Provincial Assay Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

## Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

## Accompanying the Mining Engineer

The Imperial Bank is particularly adapted to the needs of the mining engineer. Wherever he may go in the Dominion this Bank accompanies him.

Every branch of this bank—and there are 192 throughout the

Dominion—is fully equipped to render an adequate banking service. The managers of our branches in the mining areas, because of their intimate knowledge of local conditions, can impart valuable information to those engaged in the mining industry.

You will never be far from your bank account if you deposit your funds with the Imperial Bank.

## IMPERIAL BANK OF CANADA

Peleg Howland, President.

A. E. Phipps, General Manager.

## THE ECONOMIC CONFERENCE IN LONDON

Premier Mackenzie King stated last Friday, in answer to a question in the House of Commons, that an opportunity will be given to discuss the Imperial Conference and the Economic Conference to be held in London next autumn when the Supplementary Estimates are brought down. It is expected that this will be during the present week.

The Economic Conference in London has special significance for Canadians not only because our country is, outside of Britain herself, the most important part of the Empire, but for another reason. The Conference will be concerned principally with mineral resources, and Canada is the Empire's treasure-house of minerals. The attention of the Conference will be focussed on the mines, present and prospective, of this land.

Preparations are already well under way to ensure that the Canadian mineral industry shall be well represented on this important occasion. Certain of the technical officers of the Department of Mines in Ottawa have been instructed to prepare a brief, not only to cover Canada's proved and potential mineral resources in their relation to her own and the Empire's needs, but also to indicate the cases where this country must import mineral products, with a view to securing these from within the Empire.

The Federal Department of Mines has on its technical staff men well qualified to deal adequately with each and all of the mineral resources that will come up for discussion. That the Geological Survey and the Mines Branch are thus prepared to deal thoroughly and promptly with any of the wide range of minerals is due in large measure to the policy of having a specialist for each important group of minerals. Our country and its mineral industry have now, in some measure, passed through the stage of geological reconnaissance, and are entering on a second stage, where the services of the economic geologist and the mineral technologist are required to aid and direct commercial development. The Department of Mines has progressed along with the industry it is designed to serve. The Economic Conference marks a distinct phase in the progress of mining in Canada, and on this occasion our Federal Department of Mines has assumed, of its own initiative, a position of leadership that is its duty as well as its right.

The thorough preparations now under way for the Economic Conference will, no doubt, be followed in due course by equally adequate provision of personnel

round the council board. Canada will, of course, be represented by a Minister of the Crown. This Minister will have little or no personal knowledge of our mineral industry. It will, therefore, be necessary to have at the Conference, in an advisory capacity, one or more technical officers of the Department of Mines who will have all the required information at their command. Documentary evidence is seldom sufficient in such a case. The importance of the occasion demands that the best qualified members of the staff available be appointed to this duty. Only thus can we be sure that Canada will reap the full benefit from what promises to be a momentous conference.

## JOURNALISTS WILL AID MUTUAL UNDERSTANDING

Last week a party of three hundred journalists visited the collieries and steel plants at Sydney, Nova Scotia. Our correspondent for Nova Scotia, who accompanied the excursionists, gives today his impressions of the tour. His opinion, as well as that of many others, is that the first-hand information thus gained by this large group of journalists will have a decidedly beneficial result. The larger part of the people of Canada understand little either of conditions or of events in our most easterly province. The impression one gets from the regular press reports is that the mining areas are seething with disaffection and discontent. The cloud of smoke betokens fire, to be sure; but it is merely smoldering, and is kept alive only by the strenuous fanning of a small group of malcontents, influenced by an extreme form of socialistic belief.

The importance of Nova Scotia to Canada as a whole is described clearly and forcefully by Mr. F. W. Gray in an address before the visiting journalists, which we reproduce on another page. Mr. Gray is not prone to exaggeration, and we can take to heart the conclusion that without the coal of Nova Scotia, Canada could not long retain her present measure of economic independence. On this account, as well as for various other reasons, it behooves the residents of the central and western provinces to gain and retain a better understanding of the little province in the Atlantic and its inhabitants, as it is likewise the duty of the "Blue-nose" to reciprocate this interest. The personal knowledge of the three hundred visiting journalists from end to end of Canada, gained last week, will do much toward cultivating mutual understanding and toward strengthening the bonds that hold Nova Scotia within the Confederation.

### WHERE ECONOMY MIGHT BEGIN

We are frequently told, and with undeniable truth, that one of our prime duties, both nationally and individually, is to practise economy. There are two ways to make our national budget balance. One is by the imposition of additional taxation. The other is by retrenchment in expenditure. The first means an additional burden on industry which is now, after a long period of depression, picking up. Accordingly, recourse should not be had to this method, if it can possibly be avoided. Therefore we need must practise economy, the chief of the homespun virtues. We gladly acknowledge that the Dominion Government has made some attempt to set some little example in this direction, although we may remark incidentally, that the force of that example has apparently been lost on the Provincial Governments. But there is one most suitable field for the practice of retrenchment which is white already to harvest and which has been left practically untouched. We refer, of course, to the Civil Service at Ottawa—it needs no conjuror to guess that!

The whole world views with admiration Great Britain's accomplishments in budget improvement during the four years that have elapsed since the Armistice. She regained practically a balanced budget within two years after the war. Seeing that her revenue has decreased by about one third since the first peace year, due in part to lowering of taxation, how did she achieve this feat? The answer to this question is to be found in the fact that she managed to halve her expenditure. This is a very striking accomplishment and one which we in this land of unbalanced budgets may well view with envy no less than with admiration. During the post-war period Great Britain, naturally enough, made some very outstanding reductions in her expenditures for defence services. But not less striking were the reductions she contrived to effect in her expenditures for civil departments. During the past year alone \$275,000,000 was lopped off the civil expenditures, and further large economies of the same nature are being undertaken for the current fiscal year.

In France it has been much the same. During the past year the French Government cut down its staff about fifty thousand. It is true the French have not equalled the success of the British as regards attaining a balanced budget. But both countries realize that economy must begin at home—in the Civil Service. It is notorious that, at Ottawa, the Civil Service is very much over-staffed. It may be that, during the war, more civil servants were engaged at Ottawa than the requirements of the federal service warranted. It may be, on the other hand, that the increase was justified. But at any rate it is clearly the duty of the Government today, when economy in public expenditures is so imperative a necessity, to reduce the staffs as much as possible.

We do not say that the task is a pleasant or an easy one. It is the way of civil servants, in more countries than one, to block reforms that aim at putting their service on a more economical and efficient basis. Moreover, nothing is easier than to make a seemingly good case for expenditures that are really unnecessary. Heads of departments and of branches of departments have, many of them, rather a *penchant* for large staffs, the idea seemingly being that the larger the staff the more valuable and important the man at the head of it. But if the Government does its duty, it will disregard all such considerations as these, and will suppress all positions that are not demanded by the strict requirements of necessity. That is the line that our big industrial establishments took as soon as the "boom" for which the war was responsible had subsided. The Government, in the public interests, should not be more backward in using the pruning-knife than industrial concerns are in their own interests.

In coming to this conclusion, we must, however, note an exception to the rule. The Department of Mines serves the largest industry in Canada, next to agriculture. Though the progress of the mineral industry depends in notable degree upon the activities of this department, it is one of the smallest in Ottawa. Its staff is now smaller than in pre-war years. It is well administered and economically managed, and we would judge that in its case the only hope for economy is more adequate inter-departmental coöperation along certain lines. The staff of the Department of Mines is notable for faithful service. It cannot and must not be pruned. On the other hand, as soon as we can afford it, its appropriation must be substantially increased.

### A PICTURE OF KEEWATIN TIMES

Dr. H. C. Cooke's report on the Opasatika map-area, adjoining Rouyn township and including the western part of the gold belt of northwestern Quebec now being actively prospected, is published, in part, in the 1922 report of *Mining Operations in the Province of Quebec*, distributed last week. This report will be read by thousands of those interested in the new gold field, and will be studied by hundreds of mining men and prospectors engaged in its development, all of whom will form their own conclusions about it. We consider it an excellent piece of work, containing data precisely stated and clean-cut conclusions.

We wish to draw attention to another aspect of this report that might otherwise escape the reader's attention. It is written in good English; not only that, but it has a style that is rare, and that is more nearly characteristic of polished writers in Britain than it is of the half-formed attempts that are the rule among men of science on this continent.

It is to illustrate this point that we print on another

page Dr. Cooke's "historical summary". It is a word picture that brings before one's mental vision a vivid reproduction of the events of Keewatin times. Such a summary has been made a part of all the geological reports of the Survey during recent years, as has been remarked before in these columns. The historical summary now constitutes one of the most interesting, as well as most useful, parts of the reports. The Director of the Geological Survey and his staff are to be congratulated on the success they have attained already in their effort to make the Survey's reports readable, as well as authoritative and dependable.

### "A CAUTIOUS BOOM"

Business conditions in the United States are always of interest and importance to Canadians. For, in the matter of post-war booms and depressions, this country has, so far, followed, at a certain distance of time, and in less pronounced fashion, in the footsteps of the United States. In that country, a sensational burst of prosperity has been in evidence. This has resulted in very formidable wage demands being made there. And such demands we, in this country, can scarcely view with indifference; for, apart from the marked tendency in Canada, of which we have just made mention, to follow in the footsteps of the United States in such matters, the questions of wages and employment in Canada are very greatly and directly influenced by labor conditions in the land to the south of us.

Many acute observers of industrial conditions in the United States have expressed the opinion that the sudden increase in wages that has taken place will tend to increase operating costs, and ultimately the price of consumers' goods, to figures that will militate against the best interests of labor and offer a serious set-back to the general prosperity that has already begun. Naturally we have taken note of such expressions of opinion with concern; for we are not unmindful of the possibility that if there is in this country, following in the wake of the United States, a too great and too rapid increase of industrial costs, a buyers' strike may ensue. We do not want to see prosperity checked by undue inflation, and, if this is to be averted, prices must be stabilized and wages kept on a reasonable basis. Accordingly, we are glad to see in the *Business Bulletin* for May, issued by the Cleveland Trust Company, that the boom in the United States is now being tempered with common sense: "What has happened is that the era of prosperity has developed into a cautious boom", says the bank. "It is certain that the present record breaking industrial activity cannot continue indefinitely. Production is running well ahead of normal consumption. War and depression shortages are being rapidly made up, and there is no large export demand to consume excess output of manufactured goods. If the recently developed mood of cautious buying continues there will be no great price inflation, and no speculative industrial ex-

pansion such as characterized the boom of 1919 and 1920. It would be reassuring to believe that under these conditions prosperity could be conserved, at least for a long period, but probably that would not be the outcome. What might happen under those conditions is that the succeeding decline would be much less drastic than would be the case if expansion and price increases were unrestrained."

In Canada we have not yet experienced the marked business prosperity which in the United States—in some industries, at any rate — has been in evidence for two years now. But it is coming our way. And, in order that we may handle it to the best advantage, it is necessary that the boom, when it comes, should be "a cautious boom." So will it last the longer.

### THE FOREST FIRES

The newspapers are full of the subject of forest fires these days. At last the public seem to have become conscious of the fact that more millions worth of valuable timber and pulpwood are destroyed each year than would serve to balance the national budget, with plenty over for contingencies. Various means have been adopted to reduce the number of fires, but still the fires are numberless. The blame for the vast majority of these fires is now being placed where it belongs — at the door of the settler who must burn his slash in order to clear the land, and of the lumberman whose operations leave a cut-over area in such a state that a conflagration is almost inevitable. Unlike the steam locomotive, which burns its path through the forest once and for all, these first two agents of destruction and of civilization advance continuously into the forest areas. Until there is some radical change in the administration of our wooded public lands, individual carelessness is bound to result in wholesale disaster. The present attempts at reform are mere palliatives. Until policies are adopted that make each settler, lumberman, prospector or fisherman entering the woods personally responsible for the prevention of fires, we shall continue to suffer this appalling loss.

### TO THE MOSQUITO

*(Genuine apologies to Barbauld)*

Fly! I know not why thou art—  
But know that thou and I must part:  
And why on earth we ever met,  
I own to me's a secret yet.

Fly! we've been too long together,  
Through pleasant and through cloudy weather.  
Tis time to part, my duty's clear,  
I'll have to swat thee now, I fear;  
For God's sake, go! I give thee warning.  
Don't choose thy time:  
Bid me GOOD NIGHT,—and in some other clime  
Buzz thy GOOD MORNING

J. C. M.

# The Story of the Rocks in Northwestern Quebec

(Continued from H. C. COOKES' report on Opasatika Area.)

A brief historical summary of events up to this point may help to create a clear picture in the mind of the reader. The period described commences with the outpouring of the great floods of lava and their accompanying beds of tuff that now form the Keewatin. How long this period may have been, there is no means of knowing. The great thicknesses of lava, over 4 miles on Lac Seul lake, with neither bottom nor top exposed, undoubtedly required a great length of time to accumulate, but flow must have followed flow with considerable rapidity, geologically speaking, for there is rarely found between flows any weathered material, or old soil, such as would be rapidly formed had the lavas been poured out on land and left uncovered for any length of time; or any normal bedded sediments such as might be expected had the flows been poured out beneath the sea and not been covered with more lava within a few years. The Keewatin may be confidently assumed, therefore, to have been a period of almost constant extrusion, in this area at least, with an average of at least one great flow per century. The presence of beautifully bedded tuffs at the top of the series, in Rouyn township, the occasional occurrence of thinly bedded cherts between flows, and the almost universal occurrence of pillow structures in the lavas, all point to the conclusion that the extrusions were submarine, at any rate in Quebec and adjacent parts of Ontario—so that the area was covered by the sea or by some other large body of water.

After the period of extrusion ended, the lavas were raised above sea-level by mountain-building movements, and gently folded. Apparently a range of mountains, probably rather low, was formed to the north of the present Timiskaming area. Almost certainly some batholiths of granite must have been intruded into the lavas at the time of the folding, because a few pebbles of coarse granite are found in the overlying Timiskaming conglomerate.

As soon as uplift brought the rocks above sea-level, they began to be worn away by rain, running water, and the other agencies of erosion. Erosion was undoubtedly rapid, not only because of the rugged nature of the country, but also because of the lack of vegetation in that early time. The mat of roots that now covers the earth's surface wherever climatic conditions permit, and which effectively prevents running water from carrying away any large proportion of soil, was then entirely absent; and consequently every rain storm must have swept great quantities of mud, sand, and gravel into streams, to be carried to the sea. The land at that time must have been a scene of unimaginable desolation; black lava everywhere, carved no doubt by the weather into cliffs, spires, and an infinite variety of weird shapes; with the gloomy tints of basalts relieved here and there, it is true, by the lighter colours of rhyolite or dacite, but without a trace of the soft green of vegetation; with the surface everywhere piled high with blocks, boulders, and masses of rock, from between which almost every particle of soil had been swept by running water. From

the mountains rushed torrential streams, black with lava mud, and rolling quantities of gravel and boulders along their beds to the plains below.

Such were the conditions that prevailed after the uplift of the Keewatin lavas, when the deposition of the Timiskaming series commenced. The great conglomerates at the base of the series appear to have been huge, flat, fan-shaped deposits, laid down at the foot of the mountains at the mouths of outrushing streams. When the streams passed from the steep slopes of the mountains to the flat slopes of the plains, their velocity was checked, and consequently they had to drop a great part of the load they carried—naturally, the coarsest material. Their bed thus filled up, the streams were forced to break out, first in one place, then another, depositing wherever they went, until long and broad lenses of gravel of great thickness were formed.

The next event is more obscure. Perhaps great lakes were formed in some way. Perhaps the deposition of the great weights of gravel caused the land to sink locally below sea-level. In one way or the other the area where the gravels were laid down became covered with a rather shallow body of water, in which deposition took place, not of gravel, but of sands. As thousands of feet of sand were deposited, the second hypothesis is probably the correct one, and sinking of the sea-bottom kept pace, approximately, with deposition. Had the areas been lakes, they would have been filled up quickly. Here and there an occasional volcano smoked, contributing the lavas that now form local members of the Timiskaming series.

Then began the series of earth movements that uplifted the newly-formed Timiskaming series and folded them. They began with the intrusion, in small quantities, of igneous rocks, hornblende, lamprophyre, amphibolite, and diorite porphyry. These tended to form sill-like masses, rather than dykes, in the still flat-bedded sediments. Then came tremendous horizontal thrusts, so violent and long-continued that the Timiskaming strata and the underlying Keewatin lavas were turned on edge, and even overturned in places. The earth movements then gradually died away with the intrusion of various igneous rocks, gabbros of several types, granite, syenite porphyry and syenite, and the hornblende-mica lamprophyres. Most of these were small, relatively speaking, except the intrusion of the granite, which was vast and widespread. It welled up slowly in enormous masses that ate their way forward by breaking off blocks of the overlying rock, which sank in the liquid granite, or were dissolved by it. The thicknesses of rock thus stopped away by the granite are to be measured in miles, rather than in any lesser unit. In the southern part of Opasatika area, not only the 7,000 feet or more of Timiskaming series has been thus eaten away, but also all the immense underlying thicknesses of lavas, together with all the unknown floor on which the lavas were laid down.

## Electric Lamps in Cape Breton Collieries

Dominion Collieries Equipped with New Lamps and Lamp Houses

By JOHN MOFFATT

For a long time the miners of Cape Breton discussed the electric safety lamp as a possible substitute for the oil safety lamp in the collieries. Again and again representatives of the workmen and the coal operators met and talked the matter over. It was agreed by all that a lamp that could not be easily put out and that had a greater candle-power was most desirable. In searching for this lamp a number of coal operators and miners' delegates some years ago waited on Professor Sexton of the Halifax Technical School for the purpose of witnessing a demonstration of the electric lamp. The test was very simple, but just as conclusive as it was simple. Having made an explosive mixture, such as is met with in a coal mine, the Professor took a fairly large-sized electric lamp and placed it within the explosive mixture. The current was turned on and the bulb broken, when an explosion followed. A smaller lamp was next tried with the same result. This continued until a lamp of low voltage was placed in the mixture, and when the bulb was broken no explosion followed. Lamps of this low voltage were tried again and again, always with the same result. The mixed delegation of miners and operators went away feeling that the time would come when electric safety lamps would be used in the coal mines.

### 10,000 New Lamps

It was left, however, to American mine operators to put the electric lamp to a practical, every-day, working test. However, the eyes of the Nova Scotia miners were fixed on the electric safety lamp, and finally it was decided that the Edison electric safety lamp should be installed. The work of installation has now been completed at the Dominion collieries in Cape Breton, and in all 10,000 lamps have been put in to replace the Ackroid and Best oil safety lamp. The initial expenditure in remodelling the lamp houses to receive the new equipment, added to the cost of the lamps themselves, was large. However the men are well satisfied with the new lamp, and the Company feel that they have been repaid by the satisfaction of the workmen. There is now no long journey to a re-lighting station underground, for the electric lamps do not go out. The new lamp can be flashed on all parts of the workings at will, whereas the oil safety lamp could not be tilted to shine on the roof and floor without danger of putting it out or of breaking the glass. In short, there is no comparison between the oil safety and electric lamp in a coal mine. There are no shadows such as were cast by the bars of the oil lamp and all the light generated serves a useful purpose.

### Changing the Lamps

The inside walls of the remodelled lamp houses were constructed with a view to lamp delivery at the windows, and lamp charging while on the racks. Fastened to these walls are the discharging racks in which the batteries are charged, each rack accommodating 100 batteries or less and equipped with rheostats and ampere meters for regulating the charging current to one ampere, irrespective of the number of batteries being charged. For charging, where direct current is not available, or not the required voltage, a motor-generator set is installed. This consists of a 550-volt alternating current motor coupled to a 250-volt cur-

rent generator. A suitable switch board is used holding a starting and running switch, a battery and automatic switch, field rheostat, etc. An automatic switch disconnects the batteries from the generator, should the motor stop, thereby preventing the batteries from discharging. The field rheostat is used for regulating the generating current. This generator set is connected with the discharging rack by suitable charging wires.

Racks are provided for the purpose of storing the headpieces and batteries together in compartments numbered to correspond with the lamp number and miner's check. These checks are placed on the top of the charging racks, so that the actual number of men working can easily be ascertained. The checks are returned to the owners upon return of the lamp. When returned, the lamps are unlocked, headpieces are removed, and the batteries placed in charging racks, ready for charging at the normal rate of 1 ampere current for a period of eight hours.

The headpiece, after being removed from the battery, is cleaned and all necessary repairs made, then returned to the storage rack, ready for delivery next day.

Some of the lamp houses are equipped with an electrically operated water still to provide the pure water required in the lamp batteries. This water tends to evaporate from the cells during charging. The chemicals used in the batteries are examined and replenished where necessary each week.

### Using the Lamps

The average light of the battery is twelve hours, although some last twice that length of time. The solution used is caustic potash, and as it is injurious to the hands it must be handled with care. Lamps, if handled properly, will give good service, but if tampered with or roughly handled, are easily broken. Considerable trouble was experienced at the beginning with loose bulbs and also bulbs irregular in size. The use of imperfect bulbs causes flickering, which adds to the breakage both of lamps and of bulbs. When flickering occurs, the miners are inclined to tap the lamps, and this breaks the filament.

Sometimes it happens that new batteries when first filled seem to be "dead." This gives a considerable amount of trouble to lamp men without experience; but the more experienced workman knows that air carbonises the solution and reduces its strength, and when the solution takes on a black color it is thrown out.

It was generally thought that when electric safety lamps were introduced into the mines nystagmus, a disease of the eye common among miners, would disappear. This is not the case, and the miner suffering from this condition of the eye, which at certain stages forces him to abandon his underground work, has not yet been relieved of his trouble.

It was also argued in favor of the electric lamp that its stronger light, and its place on the miners' pit cap would lessen the liability of accident. Reasonable as this argument seems, it has not been proven, up to the present time, that the accident rate has decreased.

### More Light in the Mine

Probably one of the most interesting sights to be seen at the colliery is the miners gathering at the lamp house

to receive the electric lamp on the morning when it is first given out. The men are up early, in anticipation of receiving the new lamps. Standing in a queue, they pass on as the lamps are given out. Before it is placed on the cap, the miner makes a general examination, and familiarizes himself with every part of his lamp. But it is when the mine is reached that the interest increases to its height. There is no fear of stumbling while walking, as there was with the oil safety lamp. The new lamp throws light on every part of the road, and places that have been passed unseen for years are now lighted up. The first day is one of real joy, and the miner experiences the feeling that "light is good, and pleasant unto the eyes to behold."

Examination for gas cannot be made with the electric safety lamp, and it follows that examiners must be provided with some other lamp. The Koehler is the lamp in common use by the examiners of the Dominion collieries. It is a standard safety lamp, and it is very reliable. Through every section of the mine, when it is working, examiners travel for the purpose of inspection, and under this condition, miners at the face are well protected.

### L. O. X. SAFE EXPLOSIVES

Liquid Oxygen Explosives are a fine example of the dependence of engineering and industry upon scientific research. They are a type of Sprengel explosive. The novel feature is that the oxidizing agent (liquid oxygen) and the combustible substance (carbonaceous matter alone or in combination with liquid hydrocarbons or even metallic powders, and, at times, inert absorbents) are brought together immediately before use. The components separately are non-explosive. Before L. O. X. could be seriously considered for commercial work, it was necessary to produce liquid oxygen economically in large quantity and to have satisfactory containers.

Liquefaction of so-called permanent gases, air, nitrogen, oxygen and others, long baffled those who attempted it, and yet required no unusual equipment once fundamental laws were known. Repeated endeavors to liquefy these gases by pressure alone, despite development of elaborate equipment for producing pressures up to 60,000 pounds per square inch, failed; one law had been overlooked, that all gases have not only a critical pressure, but also a critical temperature. Thomas Andrews, in 1869, was first to show that there is a temperature for every gas at and below which it can be liquefied and above which it cannot be liquefied by pressure; further, that when gases heretofore regarded as permanent were at their critical temperatures, they could be liquefied by comparatively moderate pressure. Louis Cailletet, in 1877, produced the first liquid air by allowing the pressure on previously compressed air to fall 4,500 pounds per square inch, thus lowering the temperature. In 1895, or somewhat earlier, Linde in Germany, Hampson in England and Tripler in America, demonstrated that liquid air could be produced upon a large scale. Later Claude found it more economical to cause the air to do work in expanding by passing it through an engine instead of expanding it through a nozzle.

Not until 1902 did Linde demonstrate that liquid air could be separated into its constituents by passing through a special still, similar in principle to that used for separating alcohol-water mixtures. This

rendered possible the production of liquid oxygen on a large scale. To-day it is practicable to produce it upon any scale desired, employing air pressures of 900 to 3,000 pounds per square inch. Liquid oxygen boils at — 182.93 degrees Centigrade; to be used without excessive evaporation loss, satisfactory storage and transport containers were necessary. Dulong and Petit were probably first to discover that passage of heat through glass by conduction could be greatly reduced by a vacuum wall; d'Arsonval, in 1887, was first to make practical use of glass walled vacuum containers, reducing evaporation loss to 1/10 that in plain glass; it was soon discovered that a vacuum did not prevent passage of radiant heat. Dewar, in 1892, found that silvering the inner walls of vacuum chambers of containers reduced evaporation loss 1/200 of a plain glass container's loss. These containers were admirable for laboratory use, but fragile. There was needed a metallic container with low evaporation loss. Dewar discovered that properly treated charcoal, at the temperature of liquid oxygen, had the property of absorbing large quantities of gases, including air, so perfectly as to produce a very high vacuum. He secured a British patent in 1904, and in 1906 pointed out that a high vacuum could be maintained between metallic walls by this means. Modern metallic containers for liquid oxygen are rugged, highly efficient devices.

These scientific developments and actual trial of L. O. X. had been made before the world war. When Germany was cut off and it became necessary to find a substitute for large quantities of explosives used for civilian purposes, incentive came for rapid development of these new explosives.

L. O. X. under certain conditions, have distinct advantages; substantial saving in cost, greater safety, freedom from noxious gases, no possibility of explosive in ore or waste rock, which may occasion trouble; elimination of danger from drilling into unexploded charges. In cities, where large quantities of explosives are used in excavating, there is ever present danger attendant upon transportation through the streets and risk of their falling into the hands of miscreants. These hazards can be eliminated through use of L. O. X. L. O. X. have certain disadvantages. They are not so convenient in inaccessible parts of a mine, nor have they been used successfully for shaft-sinking, or under water. Under no circumstances should they be used in gaseous or dusty coal mines. We may still look forward to important improvements through research in this interesting development of a valuable commercial use for one of the constituents of the air which surrounds us.

### GOLD VEINS AND PLACERS

Placer gold may often be followed back to its source in the rocks, and this sometimes leads to valuable discoveries. Small placers sometimes occur near gold veins, having been formed by recent weathering in a glaciated country. They should be looked upon as surface enrichments which have moved a short distance from their source and not likely to be of much extent or value. But there may be places where it would pay to work these recent placers in a small way.

# ON NIGHT SHIFT

By P. B. McDONALD

The other evening one of my students told me that he was to go to work at 11 p.m. for the Pennsylvania Railroad. When I suggested that this was "the graveyard shift," he remonstrated that it did not seem so to him because he liked working at that time of night. By the gleam in his eye I could see that he was sincere and meant what he said. To my mind there came memories of night shifts that I had spent in northern Michigan as timekeeper on a shaft-sinking job, and suddenly I could see his point of view. At that time I had objected to working nights, especially during the hot summer when sleeping in daylight was difficult. Yet I had enjoyed the experience.

On night shift one comes to work, fresh and energetic at an hour when the rest of the world is tired and ready for bed. As the men congregate, there is almost an air of conspiracy at such unusual activity in the evening; a rough sociability is evident to a greater extent than in day time. Later, during the long watches of the night, the feeling of the unusual increases as the realization comes that the rest of the world is asleep, and that only a few necessary workers are awake and alert, guarding and attending to the affairs of civilization.

During the hours between midnight and daybreak the world has a strangely hushed feeling. One can stand by a bridge or a mine shaft, or look along a railroad track, and sense an aspect of modern industry not possible on other occasions. "So still it is", that, in the words of Paola and Francesca, one might almost hear:

"The sigh of all the sleepers in the world  
And all the rivers running to the sea."

On such an occasion one can reflect that among the workers and watchers of that uncanny hour are sailors straining their eyes from great ships at sea; locomotive-engineers directing trains along gleaming tracks all over the country; miners in narrow tunnels hundreds of feet underground; irregular armies of men preparing for and cleaning up after the mass of day-workers; milk-men, firemen, watchmen, market-men, telegraphers, newspaper-workers.

If the night is clear, astronomers in observatories of half the world are peering at the heavens through telescopes. If the night is foggy, ships at sea are sounding fog-horns and proceeding cautiously. If rain is falling, farmers are waking up to give the matter consideration. Whether the night is fair or stormy, huge factories and blast-furnaces in the industrial districts are busy producing, and the dark forms of men are swarming about them. To see a great industrial plant in active operation in the middle of the night, when the work-a-day world is in bed, unconscious, is to realize what a vast giant modern industry is.

No other civilization, of the dozens that have flourished upon the earth, toiled by night as do modern men. Though the Egyptian civilization lasted thousands of years longer than ours has, and though they built enormous and permanent monuments, it is not likely that they worked at night to any great extent. Probably only their priests watched out the dark hours

and noted the daily drama of the skies as the dawn-goddess pieced together the stars to make the sun-god. The Babylonian astrologers were, likewise, the only outposts of the night in their fruitful valley; they distinguished the wandering planets from which we get our institution of a seven-day week. When the Romans ruled from Scotland to the Persian Gulf, they utilized the night only for surprise attacks by their soldiers, and for carousals in the Oriental style. Through the Middle Ages, the alchemists brewed their magic at night and sought for the secrets of life during the mysterious hours before daybreak. But comparatively few men in all those past periods worked the metals or manufactured textiles or sunk shafts at night. Their lack of good artificial lights, their superstitions, and the absence of an industrial urge restrained them. Only modern man toils through the hours when Selene steps from her silver car and goes to seek Endymion:

"Silver sails all out of the west  
Under the silver moon."

While the moon looks down we manufacture soap, hoist coal, and transport fertilizer!

## R. G. E. LECKIE PASSES

Major-General Robert Gilmour Edwards Leckie, whose death in Vancouver is announced as we are going to press, was the elder son of the late Major R. G. Leckie, and a brother of Colonel J. Edwards Leckie who survives him. General Leckie was a graduate of the Royal Military College, Kingston, Ont. He served with distinction in the Boer war, had many adventures in East Africa after that war, and was the moving spirit in organizing a regiment of the Seaforth Highlanders in Vancouver at the outbreak of the World War. His career overseas was in keeping with his intrepid and indomitable nature. Although not a strong man physically, he was totally regardless of risk. He was animated by the highest ideals of British tradition. An ardent Imperialist, his conception of duty was that of willing, nay, eager, sacrifice whenever danger threatened the solidarity of the Empire.

In direct contrast to his military proclivities, Leckie, in private intercourse, was a most unassuming and retiring man. His mining career, begun in Nova Scotia, was continued in British Columbia during the days of the Rossland boom. He was a prominent figure in the early days of Cobalt, where, with his father and brother, he was actively interested in several properties. After the war he settled down to military administrative duties in Vancouver.

Only those who knew Leckie well knew also his real fineness. He did not make friends rapidly. Those he had he treasured.

Leckie was a Canadian gentleman of a kind that is only too rare, — a sensitively considerate and high-spirited soldier and mining man.

The Transvaal gold output for May 1923 amounted to 786,561 fine ounces, as compared with 743,651 fine ounces for April 1923, and 629,786 fine ounces for May 1922.

# DEVELOPMENT AT INDIAN MINES

By ALEXANDER GRAY

IN more ways than one Indian Mines, situated across Cascade Creek from the Premier Mine in the Portland Canal District of British Columbia, may be said to be a proprietary Corporation with excellent prospects and as many certainties. It has structures that keep the management thinking; fractures and cross-fractures to be studied and worked out. A diversified mineralization and the relationship of the rocks and ore exposed in the respective tunnel levels, preclude monotony. The irregularity of the ore and ore bodies and the unusual need for raises and crosscuts in the sheared zone undergoing development, make the Indian at once one of the most complicated mining ventures and one of the most attractive. Its development cannot be hastened unduly without risk, and yet the progress being made in building up ore reserves has induced the Montreal, Toronto and London owners to protect their mining position in this way:

|                     |                            |

|                     | and intervening fractions  |

## Location of Present Workings

The present mine is on the boundary line of Portland Nos. 1 and 2. At outcrop the zone being developed was traced northward into the Morn area. The contiguous claims provide acreage and opportunities for larger operations, and the Indian Mines Company will be reorganized to that end. For the time being, however, it is the intention of the management to concentrate the work in the first claims, where three tunnels and intermediate raises and crosscuts are confidently expected to provide enough ore to warrant a mill and power plant. Before next winter the directors hope to be able to complete their plans.

The Indian was not mis-named. It has had the physical attributes of majesty and perversity. Because of what is in sight and what is reasonably assured, without indulgence in overestimates, the domesticated Indian is deemed reliable enough to stand recapitalization, more equipment and further extensive development. A policy of rapid expansion was inadvisable until detailed work more fully informed the management and it was demonstrated that the vein system warranted comprehensive treatment.

## History of the Property

Staked originally in 1911, commended and condemned, approved and belittled, retained by the Clothier brothers until Portland Canal got a fresh start from the Premier Company, the Indian might have remained inactive still, had it not been for Montreal and Toronto investors. Until then, although the original area had more or less merit in its surface

showing and in its shallow workings, there does not seem to have been sufficient ore in sight to induce outside capital to take over the properties. This was not surprising, considering that the Premier ground underwent a series of rejections by influential mining men and their engineers. Eminent geologists, also, debited the claims with the doubts raised at the Premier and by the conclusions as to secondary enrichment formed at the Big Missouri. The fracturing was regarded unfavorably. The Clothiers, perhaps the best-informed mining men in the Portland Canal District, hung on because they had to. They waited eleven years — when this happened, according to the report of the British Columbia Minister of Mines for the year 1922:

"G. B. D. Turner, of New York, a mining engineer of widely-recognized ability and experience, undertook the financing and management of the property early in the year. After a careful consideration of conditions in the vicinity of the mine and examination of the tunnels, together with such open-cuts as could be cleared of snow, he then succeeded in interesting Toronto and Montreal capital, and work was started in May (1922), with R. L. Clothier as superintendent in charge, to whose energy and efficiency is due the economical development of the mine".

Really the management had to be exceptionally energetic and capable, for working capital was slow in coming. For a while the incoming interests "handled with care" the perplexing structures. They were aware they had a large, mineralized, extensively fractured contact zone, with shearings and characteristic lenses which contained a series of ore-bodies with fat and lean shoots, the lateral and vertical extent of which called for capital and an accelerated development.

The small plant installed was inadequate for the purposes of the eastern owners. Two or three drills, however, soon put enough ore in sight to more than compensate the Montreal-Toronto syndicate. The prospects were so bright a larger exploration plant was financed. Equipment and fuel oil were hauled in on the snow last winter, the Premier company with true western spirit co-operating.

## Ore-Bodies Now Developed

This enabled the management to extend the upper tunnels and do some crosscutting of the zone. A lower tunnel was started in ore and carried along for 500 feet or so. It got off the ore, but the ore body has been re-located. At outcrop, clear to one boundary, it has been shown there is ore for a distance of about 1,000 feet. Underground there seemed to be three distinct lines of mineralization. Individually the ore bodies disclosed good values. Whether the section is to be dealt with collectively or selectively, is being ascertained. More capital, therefore, had to be forthcoming; and the company reorganization is in hand to meet the new conditions. Within a year Indian Mines has emerged from a doubtful prospect, in the estimation of some, and is blocking out ore of a value in excess of the nominal capital, the higher grade being such that shipments will be made next winter. Later on a mill will

be erected and provision made for transporting concentrate.

Some time ago Mr. Turner estimated there was partly developed ore in the upper workings, which he approximately valued at almost \$2,000,000 gross. Since then the tunnels have been extended. Here is an exhibit above the main tunnel:

|           |         |
|-----------|---------|
| Section A | \$30.50 |
| " B       | 20.58   |
| " C       | 10.85   |
| " D       | 32.20   |
| " E       | 14.20   |

Although the ore above the main tunnel level is not fully blocked out, it is sure enough to warrant the present optimism. International interest, based upon information frankly imparted by the company, has made it all the easier to meet fiscal requirements without resorting to the public. The averages of the sections as enumerated above is sustained by other sections with \$14.61, \$13.09, \$15.06 and \$13.82, respectively.

#### The Latest Developments

Indian Mines Directors, therefore, have acquired more claims. They have confirmed on the surface the extension of their ore-bodies with excellent milling grade; and what is more important, they have recently proved by crosscuts the existence of parallel fissures likely to make the mine a much larger one. Besides, as at the Premier, there is cross-fissuring that is adding to the interest and the outlook. The situation to date in this, and in other respects, is presented in a recent telegraphed report from the property, sent by Mr. R. L. Clothier, as follows:

"Number one, have found two shears practically parallel about twenty-five feet apart; have been driving on west and now crosscutting to east shear at five hundred feet from portal; uncovering ore also along west shear but expect have better report from crosscut, as have drilled into ore when starting crosscut. Situation is new and very interesting and promising. Number three is three hundred ninety feet to face. Crosscutting in ore thirty dollar grade at three hundred twelve feet from portal looks like have been driving parallel to ore-body; will later drive fifty feet north, seventy feet from face and come under portal number one. Present appearance highly satisfactory. Raise from number one shows considerable ore which is improving. Junction Indian and Morn three open cuts along distance two hundred fifty feet; first cut sixteen feet, ore exposed average fourteen gold-silver; second cut, eight feet, partially across ore-body average twenty, gold-silver-lead; third cut thirteen shows high-grade ore east side but not sufficient work done to get definite average value. Think about twelve safe for present amount work done; splendid shoot ore with excellent fissure possibilities. Morn Boundary large body of about ten ore exposed practically untouched, ten to twenty feet wide."

The latest telegraphic advice is that the crosscut in the upper tunnel shows twenty-three feet of highly mineralized material, with a value in one place over a width of 2.4 feet of 4 ounces gold and 40 ounces silver. The last crosscut in the lower tunnel shows ten feet of ore.

It should be explained that the management decided some time ago to do some crosscutting while pursuing lateral development. The result was the location of the parallel lenses. Evidently the shear zone has surprises in store; and it is the increasing belief in this that causes the management to accelerate the work. The raise referred to is underneath a high-grade surface showing. The surface sampling of the profitable ore-body at the boundary of the Indian and Morn Claims, speaks for itself. Elsewhere in the Morn there is the "large body of about \$10 ore exposed, practically untouched, ten to twenty feet wide".

This shows why the owners of Indian Mines have refused several offers for control.

#### CADMIUM IN 1922\*

Cadmium is a comparatively rare metal found in small proportions in zinc ores, being present in practically all of them, to the extent of about 1 of cadmium to 200 of zinc. On account of its close relationship to zinc it is reduced along with that metal. Most of the zinc of commerce contains cadmium. "The sources of cadmium that have been utilized are zinc ores treated by fractional distillation, lead-furnace bag house fumes (the cadmium content of which is derived from zinc minerals contained in the charge of lead ore), and residues from the purification vats of electrolytic zinc plants and lithopone plants."

The United States and Upper Silesia have produced practically the whole cadmium output of the world, though a small quantity is made at electrolytic zinc plants in England, and in 1922 Belgium and Tasmania were reported to be exporting cadmium to England. The total production in the United States for 1922 was, metallic cadmium, 131,590 pounds and cadmium sulphide, 134,774 pounds. The average price of the metal was \$1.09, and of the sulphide \$1.13 a pound. Some of the cadmium is marketed as oxide and hydrate, but no figures are available for these.

The uses of cadmium and its compounds are extending. The sulphide has long been used as a yellow paint. Lately the metal has been used for electroplating by the udyllite process. The plated articles are subsequently heated for several hours at 150°-200° C, which allows the cadmium to form an alloy with the plated metal. This process has been applied to rust-proofing locks, hardware, kitchen-cabinet and refrigerator trimmings, automobile parts and accessories, and such wire products as screen wire, wire ropes and fence wire. Cadmium resists corrosion better than zinc does. The formation of the alloy results in a closely adhering covering not subject to peeling. Although started only in 1921, this process was in use in 50 plants at the end of 1922.

Another use of cadmium is in the manufacture of cadmium lithopone, which differs from ordinary lithopone in having a deep yellow to orange color, given to the pigment by cadmium sulphide.

The cadmium-vapor arc lamp gives an intense monochromatic red light useful in scientific investigations. It is interesting to note that in this lamp the cadmium is alloyed with a very small quantity of gallium, another rare metal found in zinc ores.

# NOVA SCOTIA COAL

Its Relation to Canada's Economic Development

By F. W. GRAY

Last week Mr. F. W. Gray, of the British Empire Steel Corporation, addressed the three hundred members of the Canadian Weekly Newspaper Association at a complimentary dinner in Sydney at which the Corporation was the host. His address, in full, follows:

It is not necessary to inform this audience, which is drawn from all parts of Canada and has arrived at this easternmost point after travelling over a great part of the country, that as Canadians we have a rich and vast heritage, and that the future of this country is so promising as to need no emphasis and to call for no exaggeration on our part.

## The Importance of Nova Scotia's Coal

Nevertheless, Canada suffers from one serious limitation, — one that, but for the resources of Nova Scotia, would in the long run be fatal to our hopes of national development and would some day force the absorption of Canada by the United States. I refer to the shortage of coal deposits in Eastern Canada. Between the coal fields of Nova Scotia and the fringe of the great coal fields of Alberta, there intervenes a distance of 1,800 miles, or as far as from England to the Caucasus, that is entirely without coal resources.

The coal fields of Nova Scotia, 70 per cent of the reserves of which are concentrated around this city, is a lone and singular occurrence in the Dominion. With the exception of some inferior coal in Chili and the coal field of Vancouver Island, it is the only coal deposit on either the Atlantic or the Pacific shores of the American continent. The nearest coal deposit in the United States is 800 miles away. These conditions give to the Nova Scotia field extraordinary economic and national value, out of all proportion to the actual extent of the field.

Coal is the basic raw material of modern civilization, and no nation can hope to become great, self-sustaining and independent that is without coal. It is not too much to say that the coal of Nova Scotia is the guarantee of economic independence, and consequently the guarantee of national independence, to Eastern Canada.

## Alberta's Fuel

In the West there is a large concentration of coal resources, which some day will cause Alberta to exceed the east as an industrial centre, and will bring population and wealth to the West in such a degree that it will become a predominating factor in the political economy of the Dominion.

The coal field of Nova Scotia, if its resources are properly used, will enable the East to hold its own, and will prove a main factor in holding East and West together in the indissoluble bond that the Fathers of Confederation planned for.

## Nova Scotia's War Service

Those who saw Sydney harbor in the war years, filled with vessels of war, troop-ships and transports, and saw the armed convoys leaving Sydney weekly,

with the regularity of a train service, gained illumination on the importance of the combined coal and steel industries to Canada. Had the neutrality of the United States during the years 1914 to 1917 been other than a benevolent one, Canada could not, without the coal of Nova Scotia, have provided men and ships, and could not have manufactured munitions or exported grain and war supplies.

From the Island of Cape Breton not less than 6,000 men went to the front, almost entirely volunteers and in large part composed of miners. As a result of this, the production of coal has been very much reduced.

## Nova Scotia Miners Essentially Sound

Readers of newspapers, particularly those published outside Nova Scotia, may be pardoned if they have an idea that social conditions are very disturbed in the mining districts of the province. It is probably true, as it is in all urban centres at this time, that sinister forces, originating outside Canada, are being exerted against society as it exists under British institutions; but it is scarcely necessary to state that a population with a war record like that of Cape Breton Island cannot, in the nature of things, contain any dangerous elements of disloyalty, and is, as it always was and will be, intrinsically sound at heart and able to deal with its own social problems in the manner approved of by our racial and national traditions.

The coalfield around Sydney is unique; 70 per cent of the reserve in the coal seams is under the sea. Coal is now being mined at distances exceeding 2¼ miles to sea, and 70 per cent of all the coal being mined in this district is won from under the sea. Our engineers are making technical history and their projects are of a character that will make Cape Breton renowned in the annals of mining engineering.

## Coal for Quebec and Ontario

A crying need of the provinces of Ontario and Quebec, from which a large part of this audience comes, is an assured supply of suitable fuel for domestic heating at a moderate price. The small householder cannot longer afford to pay from \$18.00 to \$22 per ton for anthracite and he cannot look for much relief in the price of anthracite, if any. Indeed, as the years go by it will become dearer and increasingly hard to obtain.

There is made here in Sydney from Sydney coal a by-product coke. This is a fuel that has all the desirable qualities of anthracite, but in greater degree; 8 tons of it is equal to 10 tons of the best quality commercial anthracite. By the erection of coke ovens in Montreal and other cities of Quebec and Ontario, it is possible to provide the householder with fuel that will cost him less than anthracite, will give him greater heat with less labor, and will relieve Canada of the necessity of importing anthracite. If this were done the mines of Nova Scotia would have an annual market for coal that would be absolutely dependable and steady; the quantity of coal mined in Nova Scotia

would increase and it would be unnecessary to send money out of the country for imported anthracite.

The manufacture of domestic coke from Nova Scotia bituminous coal in the large cities of Ontario and Quebec is one way in which Nova Scotia can help those provinces, and in turn receive very considerable assistance herself, and in combination add greatly to the wealth of the Dominion.

## EXPERIMENTS WITH RARE METALS STEELS

In a paper read at the May meeting of the American Electrochemical Society in New York, H. W. Gillett and E. I. Mack of the U. S. Bureau of Mines gave an interesting account of experiments made to test the influence of uranium, boron, titanium, zirconium, cerium, and molybdenum when used as alloying elements in heat-treated steels. The authors found that molybdenum is the only one of these elements that has a decided and consistently beneficial effect. "The most important property of molybdenum in steel is the control it gives of the development by heat-treatment of the properties desired . . . . . The best classification of steels . . . . . is on the basis of the properties that can be developed in them, or, what is almost the same thing, their relative propensity toward hardening. . . . . From this point of view, molybdenum is,—carbon excepted,—the most active and potent element used in steel. . . . . From every point of view it appears that molybdenum is an alloying element in steel, which in value stands with nickel, chromium, and vanadium." It is noteworthy that molybdenum gives the steel a strong tendency towards air-hardening, while vanadium has no pronounced power in this direction. On the other hand, vanadium so prevents a coarse-grained structure by decreasing the rate of growth of austenite during cooling, that it is safe to quench vanadium steel from high temperatures and thus get the desired great hardness.

## BOOK REVIEWS

**COPPER ORES**, by Robert Allen. — Monograph of the Imperial Institute — John Murray, Albemarle St., London, W.—221 pages — price 7s. 6d. net.

In this monograph, Mr. Robert Allen, Superintendent of the Mineral Section of the Imperial Institute, gives a comprehensive account of the occurrence, character, and uses of copper ores, with special reference to the British Empire, to which however, the author devotes only 36 pages. This seems rather scant treatment, especially in the light of the fact that 40 pages are given to a general description of copper ores. In this chapter the table on p. 19 showing the cost of producing copper (in the United States in 1918) is interesting as indicating that for ores carrying below 4 per cent. of copper, the cost of producing copper was more than the present selling price. The curves on p. 37 show that the price declined rapidly from the year 1801 (35 cents) to 1830 (22 cents), more slowly to 1850, after which there was a steady fall to 12 cents (1891-1900), after which the price rose fairly rapidly to present levels. The production curves show the phenomenal rise in output in the United States since 1891. Even before that date the United States had become the

largest producer, with Chile a poor second. For the period 1911-1920 Canada ranks fourth among five of the larger producers, exclusive of the United States.

The British Isles at one time supplied almost three-quarters of the copper output of the world, but "since about 1880 the output has been insignificant, and the copper mines are mostly of historical interest only."

The Otavi district in South West Africa is important, the Tsumeb mine having produced about 85,000 tons from which were shipped 36,280 tons of ore and concentrates averaging 13.5 per cent. copper, 29.3 per cent. lead, and 10.5 oz. silver per ton.

In Canada, British Columbia is the principal producing province, with Ontario a good second. The Flin Flon ore-body in Manitoba has a calculated tonnage of 16,000,000, containing approximately, copper, 1.9 per cent.; zinc, 3.8 per cent.; silver 1½ oz. and gold \$1.40 per ton.

In Australia the Mount Morgan mine, in Queensland opened in 1886 as a gold mine, and in 1903 discovered to run into a large deposit of copper ore with considerable gold values, in 1920 had ore reserves estimated at 3,437,000 tons with 2.59 per cent. copper and \$6 gold per ton.

In Tasmania the Mount Lyell is the only mine operating at present. It has ore reserves estimated at 2,815,000 tons, averaging about 3 per cent. copper, and considerable values in gold.

It appears from this carefully prepared account of the Empire's resources in copper ores that there may be very large reserves to draw upon, but these are largely lying idle, being mostly unable to compete with the more accessible or higher grade ores of the United States.

## NEW NICKEL-SILICON STEEL

Among the recent successes of the research department of the International Nickel Company is a new nickel-silicon steel which is stated to be unusually hard and tough, and to be susceptible of considerable commercial development. Nickel added to cast iron in amount from 2 to 4 per cent. has been found to increase its usefulness markedly, and a number of American foundries are experimenting with its use. The Company has produced a nickel-bearing type of stainless steel said to contain from 20 to 40 per cent. of nickel, 6 to 12 per cent. of chromium, and 0.25 to 2 per cent. of silicon, which can be readily machined and fabricated. One rolled sample tested gave:—Tensile strength, 100,000 lbs. per sq. in.; yield point, 60,000 lbs.; elongation in 2in., 20 per cent.; and reduction of area 50 per cent. Seamless nickel tubes are now available, made from malleable nickel, amenable to the process by which seamless tubes of copper and steel are produced.

## SOURCES OF ARSENIC

Most of the white arsenic of commerce is obtained as a by product from ores of silver, cobalt, nickel, gold, and copper; but mispickel, sulph arsenide of iron, is sometimes found in veins, with quartz gangue, in sufficient quantity to be a paying proposition for arsenic alone. The mineral is easily recognized by its great weight, its bright silvery or lead-gray color, its hardness, and the smell of garlic when the mineral strikes fire with steel.

# GEARS

A Description of the Various Kinds, their Characteristics and their Use

Copyright of Hamilton Gear and Machine Co., Toronto

## Worm Gears

The American Gear Manufacturers Association has been doing some valuable standardization work in gear practice, the following data being a result of their investigations. When ordering gear it will be well to note the improved form of worm gear rim and the standard formulae for outside diameter and width of face.

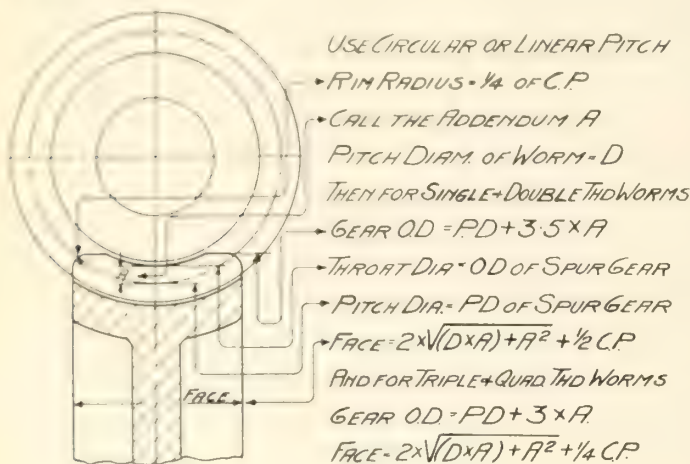

Fig. 1.

Worms with less than about 12 degrees helix angle are not reversible, but are self locking. The maximum efficiency and minimum frictional loss is found at about 45 deg. helix angle, but any angle above 25 deg. gives relatively high efficiency. Low angle worms have low efficiency on account of the large proportion of slide relative to roll between the teeth. For this reason lubrication is especially important on worm gears, and the oil must be of high enough viscosity so it will not be squeezed out by the load and leave metal-to-metal contact. Spur or bevel gears with mostly rolling contact can survive such conditions, but not so the worm. Enclosed gear cases with submerged worms are recommended. The thrust bearing is a vital point. It must be carefully designed and well lubricated.

Referring to diagram (Fig. 1) we have shown the improved form of rim section and the formula. This form of rim has a number of important practical advantages. It has additional bearing surface where it is useful i.e. in the region of the pitch lines of the worm and of the gear. It eliminates the high up-standing corners of the old style which were of very little bearing value because they were so far above the real pitch line of the gear.

Omitting these high corners cures the interference troubles between the tips of gear teeth and the worm tread. This interference was formerly always present except where these tips had been thinned away by the use of an extra long hob. In the latter case the tips were then mere idle metal. The new style rim with its wide, flat face and shallow grooves is easier and cheaper to machine, there is less metal to be removed and the rough casting weighs less. The rounded corners make it easy to handle and the flat face permits large gears to be rolled along the shop floor, which could not be done with the old style on account of battering the points. For the same reason there is less risk of damage in shipment.

## Worm Gear Enclosed Drives

Worm gears have a number of advantages over other types; also some disadvantages. They are specially adapted to high ratios of speed reduction, can be made irreversible and are quiet. These features frequently more than balance their lower mechanical efficiency.

Fig. 3.

The latter is due to power lost in sliding friction between gear and worm thread and in the thrust. For these reasons, correct design, accuracy of workmanship and ample lubrication are essential. (Fig. 3)

To meet the requirements of lubrication, to carry the thrust load and maintain rigid alignment, the modern self-contained worm gear case has been designed. It also performs two other important functions, viz: it encloses and protects all moving parts and it transmits the waste heat from the power loss in the teeth to the large outside surface where it is radiated. This matter of getting rid of the heat may be an important point in continuous operation of gears of low helix

angle and therefore low efficiency. The best all-round lubricant is heavy, steam-refined transmission oil of a viscosity high enough to maintain its lubricating value at the operating temperature. This will vary in different cases.

In order to be irreversible, gears must have a helix angle of less than ten or twelve degrees. Gears of high ratio are made for single thread worms of low helix angle. The efficiency rises with the helix angle, (though not directly proportional) to a maximum at forty-five degrees, although anything over thirty is high.

Bronze is the best material for the gear. In large gears it is economical to make only the rim of bronze. For moderate service cast iron is satisfactory. Worms are nearly always steel and frequently are hardened. For heavy duty, high class work they are hardened and ground on the threads. The ball-bearing thrust is best, but the washer thrust of alternate bronze and hardened steel is good, and is usually the correct bearing for the reverse thrust.

### Clearance

Referring to Fig. 4, it will be noticed that the whole depth of the tooth of a gear exceeds the depth that it meshes with its mate by an amount called clearance. The depth of mesh or engagement is called the working depth and is equal to the sum of the addendum of the gear and the addendum of the pinion.

Fig. 4.

Do not confuse the term clearance with backlash. The latter is the slack or play between the working surfaces of the gear and its mate measured at the pitch line.

It is important that sufficient clearance be provided so that the tooth will not bottom in the mate when meshed tightly. It is also important not to have an excessive clearance that would weaken the tooth at the root. Between these two limits, the exact amount of clearance matters very little. There are several different standards, which are valuable as production

and tool standards, but the gear user should beware of deceiving himself into thinking these are absolute.

The quality of finish in the clearance space is another point on which misunderstandings sometimes arise. As this is not a working face there is no need for a good finish, especially as it is always covered by the accumulated lubricant. Bevel gears and coarse pitch spurs are usually cut in two or more operations and frequently, especially in bevels, the marks of the stocking tool are left in the clearance. These marks do no harm.

### Bevel Gear Dimensions

There is often considerable confusion of terms in describing the size of a bevel gear, and its relation to its mate. To aid in preventing trouble the following diagram and explanation will be found of great assistance. (Fig. 5)

Fig. 5.

It must be understood that bevel gears are not calculated singly but in pairs, and even if only one of the pair is to be made, it is necessary to know the number of teeth in the mate, or the ratio of the teeth of the two gears.

The pitch is measured at the large end of the tooth. The pitch diameter and number of teeth are figured the same as for a spur gear. The outside diameter is the pitch diameter plus double the cosine of the pitch angle, divided by the diametral pitch.

Figure separately for gear and pinion. The pitch angle is found from a table of tangents. The number of teeth in a gear (or pinion) divided by the number of teeth in its mate gives the tangent of the pitch angle. The face angle is the sum of the pitch angle and the addendum angle. The addendum angle is found from the tables of sines and tangents. Twice the sine of the pitch angle divided by the number of teeth gives the tangent of the addendum angle.

### Cut Gears vs. Cast or Moulded

It is only for very coarse, slow-moving work or some jobs where the load and speed are both low and the price is a prime factor, that the use of moulded tooth gear is at all justified, and better gears pay in the long run. (Fig. 6)

Fig. 6.

Good cut gears are quiet, and cast gears are always noisy, not only because the surface is rough, but the pitch is usually far from uniform. The noise is only a demonstration of vibrations that tend to wreck the whole structure. The human efficiency and output of a man working beside a noisy drive are noticeably less than in a quiet location. This is not just theory; it is a well-known fact.

Cast gears absorb more power because of the friction of the rough surfaces and the errors in pitch and tooth thickness, which cause a varying angular velocity of the driven gear. They are weaker than the corresponding cut gear because the load is concentrated on the high spots of the rough and often badly shaped tooth face. These high spots are quite as likely to be at a corner as anywhere else, giving maximum stress and liability to breakage. When worn smooth the cast gear suffers from excessive backlash and loss of tooth form.

None of these difficulties arise with gears that have correctly cut teeth. On herringbone gears with generated helical teeth the action is especially perfect. There is no noise, no shock and when mounted rigidly in an enclosed oil-case this is the highest type of power transmission apparatus.

(to be continued)

### "ELEKTRON ALLOYS"

"Elektron" is the name of a group of alloys, whose composition approximates to 95% magnesium, 4.5% zinc and 0.5% copper, the yield point being about 12 tons, with ultimate strength of some 18 tons per sq. in. and elongation about 20% on two inches. The appearance of elektron is much like that of aluminium but without the bluish tint. The melting point is 630–650° C., and melting must be done in iron, and not graphite, crucibles. It is subject to atmospheric corrosion but soon acquires a protective film of oxide. Its most distinguishing feature is its extremely low specific gravity, which is about 1.80 as compared with 2.67 for pure aluminium. This property makes it of value for special purposes, and it would appear to be particularly suitable for aircraft, at least for accessories if not for the more vital parts.

Dr. Thomas, in a recent issue of *Metallkunde*, discussing the objections raised to the use of the alloy, pointed out that the danger of inflammability during casting can be easily avoided by reasonable care. In the molten condition, "Elektron" will decompose water into its explosive gases, but there seems to be no reason why in that state it should be brought into contact with water. The dust arising from machining is undoubtedly explosive if allowed to accumulate.

Magnesium, the base of this and similar alloys, is not, as its high price would suggest, a rare metal, as magnesium minerals are very plentiful in the crust of the earth. There seems to be no reason why the magnesium chloride of sea water and the vast magnesian limestone or dolomite formations should not in future furnish the raw materials, and such sources are of course quite inexhaustible.—The Metal Industry.

### MAGNESIUM ALLOYS

Ultra-light alloys are those having a specific gravity of less than 2, the light alloys and metals ranging from 2 to 3. Magnesium, with a specific gravity of 1.72, is the only commercial metal for the production of the former as above defined.

One producer each in France, England and Germany, at present turns out magnesium, the method being that of electrolysis from a molten mixture of the chlorides of magnesium and potassium. The Ashcroft process uses a double electrolyte and has recourse to an intermediary lead-magnesium alloy. German so-called "Elektron" alloys, up till the past few years, contained chiefly zinc. At present the ultra-light alloys are, for the most part, ternary zinc-aluminium-magnesium alloys. For internal combustion engine pistons, alloys are used having 12% copper.

The ultra-light alloys, with the mechanical characteristics they at present possess, offer great advantages from the point of view of weight reduction in structures. It is illusory to try to increase the resistance and elastic limits of such alloys so long as one does not raise the moduli, according to certain definite proportions. The possibility of sufficiently increasing the moduli of these alloys does not appear to be very extensive.

To utilize these alloys for minute and long thin parts would be a grave error when mechanical properties come into question, and for constructional purposes it would be necessary to entirely modify our conceptions in a direction which should take due regard of the nature and limitations of the material under review.—Le Génie Civil.

### THE DEEPEST MINE

The St. John del Rey mine in Brazil is now being worked at a depth of 6,726 feet below the surface, the deepest point to which human beings have as yet penetrated the crust of our globe. As the temperature of the wall-rock at this depth is high (117 deg. F.) it has been found necessary to cool the ventilating air at the surface by a special refrigerating device. The mine has been operated by the present English company since 1837. The ore is a mixture, in approximately equal proportions, of quartz, ankerite, and pyrrhotite, the last containing good gold values.

### SALT IN 1922

According to a statement issued by the United States Geological Survey, the quantity of salt produced and marketed in the United States in 1922 (classed by varieties) was as follows: evaporated, 2,276,683 short tons; in brine, 2,569,042 short tons; and rack salt, 1,947,124 short tons. The total value was \$27,464,839. These figures show an increase of 36 per cent. in quantity but of only 12 per cent. in value over those for 1921. The producers of common salt reported also the recovery and sale of calcium-magnesium chloride amounting to 33,067 short tons, valued at \$571,326, and bromine and bromides equivalent in the aggregate to 1,005,174 pounds of bromine, valued at \$150,668.

### PLACERS IN GLACIATED REGIONS

In glaciated regions, gold placers may have been scattered by the ice-action; or as at Cedar Creek, B.C., the placer may have been left undisturbed, but covered with glacial gravel. In the Cariboo district this covering is so deep in some parts that valuable placers long escaped discovery. While the time since the close of the glacial period has been too short for the formation of important placers by erosion, some payable placers have been formed by resorting of the gravels that have been scattered by the glaciers.

# THE MINING DISTRICTS

By THE JOURNAL'S CORRESPONDENTS

## BRITISH COLUMBIA

**Granby Properties Inspected.** — Col. J. T. Crabbe, president of the Granby Consolidated Mining & Smelting Co., is visiting British Columbia. He is making a personal inspection, accompanied by Mr. H. S. Munroe, general manager, of the company's properties in this Province. Col. Crabbe expresses himself as pleased with the company's achievements in 1922. There was produced over 30,000,000 pounds of copper, 405,471 ounces of silver and 6,996 ounces of gold. The average price obtained for copper was 13½ cents and the average cost of operation was 9.15 cents per pound. Fine dust from Anyox treated at the Tacoma smelter yielded nearly 2,500,000 pounds of copper and 37,033 ounces of silver. The low cost of operation had placed the company in a favorable position with its competitors. He was pleased, also, with the colliery operations at Cassidy, some 220,013 tons of coal having been produced during the year and either marketed or consumed by the company.

**Survey of Copper Mountain.** — Dr. Victor Dolmage, head of the British Columbia Branch of the Geological Survey of Canada, has left Vancouver to make a survey of the mineralized portion of Copper Mountain. It is here that the ore-bodies are located that will be exploited by the Granby Consolidated Mining & Smelting Co. George F. Barnwell, professor of mineralogy in the Missouri School of Mines; William Smith-eringale, of the University of B. C.; and J. Buckle, of McGill University, will accompany the party.

**B. C. Arsenic for Japan.** — British interests are reported to be trying to obtain 1,000 tons a month of arsenic for shipment to Japan. There are deposits of arsenic in this Province but at present only one producer, the Hedley Gold Mining Co., whose last year's output of some 500 tons realized about \$100,000.

**Trail Ore Receipts.** — Ore receipts at the Trail Smelter, Consolidated Mining & Smelting Co. of Canada, for the first week in June aggregated 7,368 tons, which brings the total for the year to date up to 201,038 tons. Detailed shipments for the week follow:

|                                  | Tons  |
|----------------------------------|-------|
| Alamo, Alamo . . . . .           | 44    |
| Bell, Beaverdell . . . . .       | 36    |
| Company Mines . . . . .          | 6,814 |
| Emerald, Salmo . . . . .         | 33    |
| Knob Hill, Republic. Wn. . . . . | 273   |
| Silversmith, Sandon . . . . .    | 176   |
| Standard, Silvertown . . . . .   | 28    |
|                                  | 7,384 |

L. K. Armstrong, of Spokane, Wn., secretary of the Columbia Section of the American Institute of Mining & Metallurgy, has been inspecting some mining properties in the Kaslo District, B. C.

**Stem-Winder to Resume Operations.** — M. S. Davys, of Kaslo, contemplates the re-opening of the Stem-Winder Group of mineral claims in the Cranbrook district. There is a large body of ore exposed on this

property, which has been a producer in the past and, if the price of zinc holds, it is thought that it may be made to yield profits.

**Dr. Hanson Suggests Consolidation.** — Dr. George Hanson, of the Geological Survey of Canada, has expressed the view that the Alice Arm District, may look forward to a bright future from a mining standpoint. The Dolly Varden, he is quoted as saying, is far from a "done" mine, and he advocates the consolidation and operation of the larger low-grade silver properties adjacent to and including that mine. This would involve the installation of a transportation system of short tram lines from some five or six properties surrounding the Dolly Varden to a centrally located concentrator. He also suggested that profits may be obtained by the exploitation of small high grade silver veins as now is being done on the Esperanza Mine.

**Coal Output Lower.** — Coal production in British Columbia fell off materially in the month of May as compared with April, the difference being some 28,242 tons. Vancouver Island collieries are responsible, to a large extent, for the drop, their output in April being 115,628 tons and in May 97,367 tons, a margin of 18,261 tons. In the Nicola-Princeton field the chief producer, Coalmont Collieries, mined about the same tonnage in May as in April and in the Crow's Nest Pass Coal Field there was a slight decline, about 7,415 tons.

From this it is clear that the sharp fall is due to conditions on the coast. Early in May it was apparent that the collieries were finding the market weak, because the mines were worked on short time and there was a general tendency to cut down output. The explanation generally given is the lack of demand for coal for domestic use with the advent of warmer weather; but this does not fully meet the situation, as the bunker trade has been very slack. It is reported, however, that the collieries recently have renewed some large contracts and already there are signs of improvement.

|                                              | Tons    |
|----------------------------------------------|---------|
| Production figures for May in detail follow: |         |
| Vancouver Island . . . . .                   | 97,367  |
| Nicola-Princeton . . . . .                   | 15,709  |
| Crow's Nest Pass . . . . .                   | 49,236  |
|                                              | 162,312 |

**Picnics for the Miners.** — The annual employees' picnics are much enjoyed and keenly anticipated events by the coal miners of the Canadian Collieries (D) Ltd. and the Western Fuel Corporation of Canada. On these occasions the men are given a full day's holiday, which is spent on ground adjacent to the Companies' main plant, and men, women, and children, employers and employees, devote themselves to having a good time. There are all manner of sports, group and individual competitions, and plenty of appetizing things to eat and satisfying liquids to drink. Dates for this year's events already have been announced. The Western Fuel Corporation's employees will hold

their plants on the 30th June at Newcastle Island and the outing of the Canadian Collieries (D) Ltd will be held, at a place not yet announced, on the 21st July.

**Bore holes near Nanaimo.** — It is announced that boring tests carried on by the Canadian Collieries (D) Ltd. in the Sable River District near Nanaimo, Vancouver Island, have demonstrated that the coal beds of this region are capable of a production of 3,000 tons a day for 300 years.

**Cassidy does Well.** — Col. J. T. Crabbe, president of the Granby Mining & Smelting Co., who has been inspecting the company's holdings in British Columbia, expresses satisfaction with the result of operations at the Cassidy Collieries, Vancouver Island. He states that the 220,013 tons of coal produced at Cassidy last year were won at a low cost per ton and that coal raising, both to supply the fuel needs of the company and for general market purposes, is becoming a more important branch of the operations of the company in this province.

**Crow's Nest Annual Meeting.** — The annual meeting of the Crow's Nest Pass Coal Co. Ltd. was held at Fernie B.C. on June 8th last when directors were elected as follows: Messrs W. R. Wilson, H. B. McGiverin, W. H. Robinson, E. P. Earle, A. H. McNeill, J. T. Maher, F. F. Edgar, L. C. Gilman, and Dr. G. W. Howland. Officers were elected as follows: President, W. R. Wilson; vice president, H. B. McGiverin; vice-president, W. H. Robinson; treasurer, A. Klauer; Comptroller, G. H. Hess Jr.; secretary, J. S. Irvine. The report of President Wilson for 1922 indicated a balance to profit and loss account at the end of 1921 of \$84,857.88, after payment of Federal taxation, etc. To this was added \$213,959.05, this being the company's net profits from all sources of the operations of the year 1922. After making provision for the Dominion income tax for 1922, amounting to \$21,001.27, there was left a total of \$192,957.78. "During the year", Mr. Wilson continues, "the directors have paid four dividends of 1½ per cent. each, making a total of 6 per cent for the year, amounting in all to \$372,690.00 leaving a debit balance of \$94,874.34 to be carried forward and provided for during 1923." It is shown that the Company spent last year \$35,293.80 on improvements and that the coal mined in 1922 totalled 569,339.14 tons as against 774,847 tons mined in 1921. The coke produced was 46,368 tons compared with 66,569 tons in 1921. Mr. Wilson concludes: "The decreased production in each case has been attributable to the five months' strike."

The President's address in moving the adoption of his report is of special interest as setting out the conditions that prevailed in the coal districts last year, and those now facing coal mine operators in this part of the Province. He said:

"In moving the adoption of the report, I am in the unpleasant position of having to state that the operations of 1922 were seriously affected through contentions about international coal mine wages.

"In 1921, our wage scale agreement expired on the 31st of March, 1922, at a time when the chief co-dependent industries on coal had come to realize the necessity for accepting a lower ratio of wages for the purpose of helping to re-establish such industries. It was, therefore, reasonable to presume that those especially engaged in the production of coal would take the same broad view of things, and at least recognize

the fundamental necessity of agreeing to the acceptance of a reduced scale of wages for coal mining work that would be in harmony with what had been done by other classes of labor that were engaged in other co-dependent industries. These expectations were not realized, for those responsible for the guidance of coal mine labor on this continent specifically refused to accept the belief that any concessions in the form of reduced wages for coal mining communities were necessary at that time. The controversy continued from April 1st, 1922, to the latter part of August of the same year, or about five months, during which time this company's mines were not only unproductive, but were under serious daily cost in the form of caring for continual mine drainage and general maintenance charges. The employees of the company lost during the five months of the strike about \$1,200,000 in wages, and the company correspondingly endured the loss that resulted from the maintaining of idle plants for five months.

"After five months' contention, a temporary understanding was reached between the United Mine Workers of America, and the operators of this district, to re-open the mines and carry on operations at the 1921 wage scale rates until April 1st, 1923. During March, 1923, it was further agreed by the interested parties to allow 1921 and 1922 wage scale agreements to continue for one more year, which understanding we are now working under.

"From what I have stated, it may be noted that this district is still continuing to pay the high scale of coal mine wages stimulated by the exigencies of the late war. The result of these high wages and correspondingly high cost of production is creating a new set of adverse and discouraging conditions for this district in particular, for through the high cost of coal fuel, the railroads that this company in particular largely depended upon for the economic operation are replacing coal fuel by oil fuel, which they have only done after patiently waiting for two years to see coal prices return to more normal selling prices. In addition to this, smelters are prevented from accepting the lower grade of ores because of the abnormally high prices of coke due to the high wages. I may here, before closing my remarks, note that when wages are increased in this district, the cost of production becomes magnified over and above the cost of coal mining fields that are operating under more favorable physical conditions, such as uniformity of structural coal bedding, good overlapping roof and greater freedom from dangerous gas generation. For example, the day wage men in our mining fields here, due to the abnormal physical conditions we have to deal with, will exceed the day wage labor employed under the more favorable physical and structural conditions in Western Pennsylvania and West Virginia by from 100 to 300 per cent., which necessary and excessive application of day labor affects the cost of production in about the following corresponding ratio:

|                                                                    |     |
|--------------------------------------------------------------------|-----|
| Western Pennsylvania percentage of day men average about . . . . . | 30% |
| Virginia percentage of day men average about . . . . .             | 25% |
| This District percentage of day men average about . . . . .        | 60% |

"During the seven months' operations the mines produced 569,339 tons of coal, the Michel ovens pro-

ducing only 46,368 tons of coke. The low production is largely accounted for by five months' suspension of operations, or strike.

"In co-relation to the stated production, the following corresponding development work was done in the Mines during the year:

|                                     |              |
|-------------------------------------|--------------|
| At Coal Creek Mines:                |              |
| Narrow Development work amounted to | 44,115 feet: |
| At Michel Mines:                    |              |
| Development work amounted to        | 6,225        |
| Total for all Mines during 1922     | 50,340       |

"The preceding figures fully maintain the developed capacity of all mines up to 4,500 tons per day of eight hours operations. It may here be interesting to mention that at the close of 1922 the combined measurements of all the main roadways in the Company's Mines amounted to 164,126 feet, or 31 miles.

"During the year, the Company installed 16,420 feet of new water lines for spraying the working places, or for the purpose of allaying the light floating coal dust generated in the working faces.

"I may further remark that during the year, the United States Government have placed a reciprocal tariff against Canadian coal of 53 cents per ton on all grades of coal except slack that goes through a three-quarter inch screen, and 14 cents per ton on the three-quarter inch slack. This tax, it is needless for me to state, is proving to be a further detriment to the production at these mines".

**Hope for Alberta Coal Shipments.** — Howard Stutchbury, coal commissioner for the Province of Alberta, has returned from Ontario and other points in Eastern Canada highly pleased with the reception given him in his endeavor to establish a market for coals of Alberta. A good market for Alberta domestic coals can be developed in Eastern Canada providing a competitive freight rate can be secured. This is Mr. Stutchbury's opinion and he states that the effort to obtain the required transportation adjustments is to be continued until it meets with success or is definitely refused. He estimates that the importation of coal for all purposes into Canada from the United States represents an expenditure of over one hundred million dollars a year. These funds and their possibilities for the building up of this new country are lost unnecessarily, he argues. The retention of this huge sum would stabilize both the labor and industrial situations of Alberta.

**June Output to be Larger.** — Late reports from Vancouver Island Collieries prove that a decided change has set in this month and that the production for June is likely to be considerably in excess of that of last month. No. 5 Mine, South Wellington, Canadian Collieries (D) Ltd., which has been shut down temporarily is operating again, some 150 men being employed. Practically all the other mines are working well up to capacity.

It is also stated that the new slopes in No. 5 Mine, Cumberland, Canadian Collieries (D) Ltd., upon which the company has been working for several weeks, have struck coal. One of these slopes went through rock for a distance of 450 feet. These improvements will facilitate the mining of coal in this field and the result should be apparent shortly in an increase in output.

## NOVA SCOTIA

**Journalists Visit Sydney.** — To learn the tastes and the needs of certain sections of the Canadian public, three hundred delegates of the Canadian Weekly Newspaper Association gathered in Halifax last week and after completing their business enjoyed a delightful visit to the historic land of Evangeline, now hidden in fragrant apple blossoms. Leaving Annapolis, this group of journalists steamed into Sydney station, where they were met at the train by citizens of Sydney and the colliery towns, and taken out to see not only the wonderful scenery round about Sydney, but the more wonderful industries of the Sydney steel plant and the collieries.

As these happy men and women looked out on the great stretch of waters in this almost land-locked harbor, which sheltered the convoys of war days, they were loud in exclamations of wonder and praise, and outspoken as to their growing appreciation of their own country, its magnificence and its resources. The program arranged beforehand led them through the steel works with its gigantic mills, its great blast and open hearth furnaces, and its many other departments. From here the party had a run out to the coal mines at New Waterford. The route lies along the side of Sydney harbor, and on this beautiful June morning, the water sparkled and shimmered in the summer sun.

**Visiting the Mines.** — At the collieries the visitors had an opportunity to study the fuel problem of Canada on the ground. Questions were freely asked and answered, and in a few hours the men who make and mould to so great an extent the public opinion of Canada fully understood one feature at least of this pressing problem. Here on the surface lay large piles of timber, used to support the roof underground when the coal is removed. At other points were large stocks of material such as gravel, sand and stone for use both above and below ground. The compressor houses with their many engines, each developing 600 H.P., to supply the mining machines underground, and the great pipe lines used to carry this compressed air miles into the mines, the boiler plants, the bank-heads with their picking belts and screens for cleaning and assorting coal, the fans for ventilating the mine, the haulage engines for drawing the coal out of the collieries, all are part of the surface equipment. The machine shops, the forges and repair shops, the ware houses, bath houses, first aid stations, and stables, are all necessary adjuncts to a first-class colliery. These were all visited, after which many went into the mine to see the underground workings. But all the time, the mind and eye were busy and the usual conclusion expressed was that it requires much money to open up a coal mine. When in answer to a direct question as to the cost, it was stated that to equip and develop a single colliery costs about \$2,000,000, no surprise was expressed, for the point had been demonstrated.

To most of the visitors it was all new and strange, but very illuminating. The depth of the mine, which runs out under the sea two miles, and the quality of the coal were discussed. Many souvenirs were carried away from No. 12 Colliery in the shape of small pieces of coal. New Waterford district has a splendid quality of coal; its lustre catches the eye and leaves no doubt in the mind that it ranks high as a fuel.

**The Company Houses.** — Turning towards the company houses, a desire was expressed to visit these. The nearest house was entered, and the good lady was informed very courteously that gentlemen much interested in the social welfare of the Canadian people would like to see through her house. The request was graciously granted. The house was semi-detached, or what is known in the colliery districts as a double house. It stood fenced in, within a large yard, with sufficient ground for a garden large enough to satisfy any workman. In the rear stood a garage. The first room entered was nicely furnished and spotlessly clean and contained a piano and victrola. A well-painted oak stove stood in the kitchen, and we had a peep at the well-stocked pantry. Upstairs were four bed-rooms. The house had electric light, and rented for \$6.00 per month. It was remarked that few gardens were planted, but a retort from one of the visitors settled the point when he pointed to the many garages and autos possessed by miners, and consequently the lack of time to care for a garden.

Another house was entered in another village. It stood in a plot of ground covering three-eighths of an acre, and was fenced in. In the rear was a small barn and coal house built by the company. The barn was used as a garage. This house was self-contained, with four large rooms downstairs and five up. It had electric light and running water, and was rented for \$6.00 per month. Here, again, the occupants had well-furnished rooms, a piano and victrola and a nice library. The owner possessed an auto and he was one of four miners living quite close together, who owned up-to-date cars.

"What are the miners kicking about? and what is all this stuff that we have been reading about in the papers?" inquired one of the editors. "How much do these men earn?" inquired another; and when told that miners that cut coal earn all the way from six to ten dollars per day, and sometimes much more, the common exclamation was, "Why, they all earn more money than we do! The people of Canada ought to know the true circumstances of the Nova Scotia miners. No doubt they are entitled to good wages, but why should they continue to agitate and keep the Province in an uproar?"

#### Complimentary Dinner at Sydney

A spin to Sydney over a road that ranks with any in Canada brought the party back to the Yacht Club, in time to get ready for luncheon. The visitors were the guests of the British Empire Steel Corporation and the catering was in the hands of the I. O. D. E., who reached the hearts of all with their kind attentions. So while the heart throbbed and thrilled to the patriotic strains of our National Anthem and songs, the feast was spread and heartily enjoyed. A pleasing souvenir in the form of steel cuff-links bearing the letters B. E. S. Co. was found in a small envelope placed beside each plate.

W. H. Bishoff, General Superintendent, Dominion Iron and Steel Company acted as toast-master, and his breezy pleasant manner at once placed everyone at ease. After speeches by the officers of the Press Association, who emphasized the national side of Canadian life, and told of the great work accomplished by means of the weekly newspaper, which papers were treasured in almost every home. The industrial side was referred to. Mr. W. F. Gray gave a most

lucid talk on the fuel problem of Canada as he saw it. This was one of Mr. Gray's finest efforts. He had a splendid audience, all eager to catch every word and syllable he let fall. He was quick to recognize the opportunity, and in rising to the occasion he placed the case of the coal and steel industry of Nova Scotia in a light never before realized by the great majority who listened to him.

T. J. Brown, Deputy Minister of Mines, who had already prepared the way for the visitors by writing a most delightful description of Cape Breton in the "Chronicle's" Tourist Edition, and who had accompanied the party all the way from Halifax, in an eloquent and glowing speech emphasized the necessity of having the promises made at Confederation faithfully carried out by the sister provinces. The "jewel in the swine's snout", as he termed his native province of Nova Scotia, must not be forgotten. The diamonds may be black, but they have a lustre all their own, and form part of the great mineral wealth, without which Canada would be poor indeed.

With flags flying, streamers fluttering in the breeze, and all hands singing "O Canada", the party sailed down Sydney Harbor, through the beautiful Bras d'Or Lakes and when the symmetrical Bird Islands, which sentinel the enchanted land, had been passed, the imagination was captured by the splendid scenery of the headwaters of the Bras d'Or Lake which

"In all its length far winding lay,

In promontory, creek and bay."

Landing at Iona, the party moved on to Prince Edward Island, the home of the New England Royalist. Here their descendants till the soil, fertile fields give forth the golden grain, and this once black spot in the Atlantic is now called the "Garden of the Gulf".

**Successful Candidates at Examinations.**—Of the 249 candidates who went up for the Mining Examinations fifteen passed for mine managers, forty-four underground managers, forty-seven overmen, and ten examiners; first-class engineers six, second-class six, third-class fifty-five. The examiners state that the educational standard of the younger men passing through the schools is very much higher than when examinations first began to take place. The work is done very much better and the examiners feel proud of the work of the applicants.

#### FALL MEETING OF ELECTROCHEMICAL SOCIETY

The next meeting of the American Electrochemical Society is to be held in Dayton, Ohio, on September 27th to 29th. The papers will include a symposium on "Recent Progress in Electrolytic Refining," under the chairmanship of F. R. Pyne, of the United States Metals Refining Co. There will be an innovation, consisting of round table discussions of electric furnace brass foundry practice, organic electrochemistry, chlorine and electroplating. Visits will be made to local plants.

#### PERIDOT

This is the jeweller's name for crystals of olivine. When clear, transparent, and free from flaws, they are of value as gems. They may be found in basic igneous rocks such as peridotite, and in crystalline limestone.

# PROVINCE OF QUEBEC

## MINES BRANCH

Department of Colonization, Mines and Fisheries

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, etc.

### MINISTER OF COLONIZATION, MINES AND FISHERIES, QUEBEC

**MINER'S CERTIFICATES.** First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is \$10 and is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

**WORKING CONDITIONS.** During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

**SIX MONTHS AFTER STAKING.** At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

**MINING LICENSE.** The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is \$10.00 an acre per year, and a fee of \$10.00 on issue. It is valid for one year and is renewable on the same terms. The holder must produce an affidavit that during the year work has been performed to the extent of at least twenty-five days' labour on each forty acres.

**MINING CONCESSION.** Notwithstanding the above, a mining concession may be acquired at any time at the rate of \$5 an acre for SUPERIOR METALS, and \$3 an acre for INFERIOR MINERALS.

The attention of prospectors is especially called to the territory in the North-Western part of the Province of Quebec north of the height of land, where important mineralized belts are known to exist.

**PROVINCIAL LABORATORY.** Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, Montreal, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

**HONORABLE J. E. PERRAULT,**

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

# BRITISH COLUMBIA

## The Mineral Province of Western Canada

Has produced Minerals valued as follows Placer Gold, \$76,542,203; Lode Gold, \$109,647,661; Silver, \$59,814,266; Lead, \$51,810,891; Copper, \$170,723,242; Zinc, \$24,625,839; Coal and Coke, \$238,289,565; Building Stone, Brick Cement, etc., \$36,605,942; Miscellaneous Minerals, \$1,358,839; Making its mineral production to the end of 1922 show an

## Aggregate Value of \$734,259,619

The substantial progress of the Mining Industry of this Province is strikingly exhibited in the following figures, which show the value of production for successive five-year periods: For all years 1895, inclusive \$94,547,241; for five years, 1896-1900, \$57,605,967; for five years, 1901-1905, \$96,717,068; for five years, 1906-1910, \$125,534,474; for five years, 1911-1915, \$142,072,603; for 5 years 1915-1920, \$189,922,725; 1921, \$28,066,641; for the year 1922, \$35,158,843.

## Production During last ten years, \$339,280,940

Lode-mining has only been in progress for about twenty-five years, and not 20 per cent. of the Province has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those of any other Province in the Dominion, or any Colony in the British Empire.

Mineral locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with Mining Reports and Maps, may be obtained gratis by addressing.

VICTORIA, British Columbia  
THE HON. THE MINISTER OF MINES.

# What Angle Compound Compressors Will Do For You:

1. Provide a constant, reliable air power supply.
2. Cut in half the floor space devoted to Compressors.
3. Cut in half your foundation and installation charges.
4. Permit ready adaptation to any form or arrangement of power drive.
5. Lower your horsepower per 100 feet of air compressed.
6. Operate efficiently at partial loads.
7. In the "twin" direct motor driven units, avoid excessive peaks in the power inflow.
8. Require minimum attendance and repair.

Ask for an "Angle Compound" proposal  
on your new compressor

# MORSE

# CHAINS

O. W. Ludwig, Plant Superintendent of the  
Raymond Lead Co., Chicago, says:

"Thirteen years of service without a repair is our experience with two 100 H.P. and ten 20 H.P. Morse Silent Chain Drives.

"When we moved into our present plant thirteen years ago, we installed the present Morse equipment of silent chains for our two lead mills and ten hydraulic pumps. We had always previously used leather belts, but not without considerable trouble. For instance, if the operator was not careful—and gave the motors too great a load, the leather belt would slip and in some cases burn out. While with the Morse Chain Drive we overload them at times up to 15 H.P. without the slightest trouble.

"When we used leather belts on the hydraulic pumps, if a pump packing suddenly gave way, the water would squirt all over the pump as well as adjoining pumps, causing the leather belts to get wet. This often necessitated a shut-down on 3 to 4 pumps to dry out each belt, thus causing a loss of time by the men, which resulted many times in paying overtime to catch up on the work. Of course, with our Morse Chain Drive we have no such trouble—this positive drive prevents slippage and is not affected by water.

"Leather belts lasted us 2 to 3 years at the most, while our Morse Chain Drives have already lasted 3 to 4 times that long and seem good for many more years. So Morse Drives have cut our expense materially, speeded up production, cut out overtime wages and saved floor space, for they operate on shorter centers."

A few of the Morse chains in use at the Raymond Lead plant

Using chain drives speeds up production, cuts belt expense and overtime wages and operates with practically no repairs.
